Preface to the First Edition

Following normal custom, the prefaces to the first and second editions are included in full. However, some passages are misleading because of changes made in the third edition. These passages are enclosed in square brackets.

Galois theory is a showpiece of mathematical unification, bringing together several different branches of the subject and creating a powerful machine for the study of problems of considerable historical and mathematical importance. This book is an attempt to present the theory in such a light, and in a manner suitable for second- and third-year undergraduates.

The central theme is the application of the Galois group to the quintic equation. As well as the traditional approach by way of the “general” polynomial equation I have included a direct approach which demonstrates the insolvability by radicals of a specific quintic polynomial with integer coefficients, which I feel is a more convincing result. [The abstract Galois theory is set in the context of arbitrary field extensions, rather than just subfields of the complex numbers; the resulting gain in generality more than compensates for the extra work required.] Other topics covered are the problems of duplicating the cube, trisecting the angle, and squaring the circle; the construction of regular polygons, the solution of cubic and quartic equations, the structure of finite fields; and the “fundamental theorem of algebra.” [The last is proved by almost purely algebraic methods, and provides an interesting application of Sylow theory.]

In order to make the treatment as self-contained as possible, and to bring together all the relevant material in a single volume, I have included several digressions. The most important of these is a proof of the transcendence of π, which all mathematicians should see at least once in their lives. There is a discussion of Fermat numbers to emphasize that the problem of regular polygons, although reduced to a simple-looking question in number theory, is by no means completely solved. A construction for the regular 17-gon is given, on the grounds that such an unintuitive result requires more than just an existence proof.

Much of the motivation for the subject is historical, and I have taken the opportunity to weave historical comments into the body of the book where appropriate. There are two sections of purely historical matter: a short sketch of the history of polynomials, and a biography of Évariste Galois. The latter is culled from several sources (listed in the references) [of which by far the most useful and accurate is that of Dupuy (1896)].

I have tried to give plenty of examples in the text to illustrate the general theory, and have devoted one chapter to a detailed study of the Galois group of a particular field extension. [There are nearly two hundred exercises, with twenty harder ones for the more advanced student.]
Many people have helped, advised, or otherwise influenced me in writing this book, and I am suitably grateful to them. In particular my thanks are due to Rolph Schwarzenberger and David Tall, who read successive drafts of the manuscript; to Len Bulmer and the staff of the University of Warwick Library for locating documents relevant to the historical aspects of the subject; to Ronnie Brown for editorial guidance and much good advice; and to the referee who pointed out a multitude of sins of omission and commission on my part, whose name I fear will forever remain a mystery to me, owing to the system of secrecy without which referees would be in continual danger of violent retribution from indignant authors.

Preface to the Second Edition

It is sixteen years since the first edition of Galois Theory appeared. Classical Galois theory is not the kind of subject that undergoes tremendous revolutions, and a large part of the first edition remains intact in this, its successor. Nevertheless, a certain thinning at the temples and creaking of the joints have become apparent, and some rejuvenation is in order.

The main changes in this edition are the addition of an [introductory] overview and a chapter on the calculation of Galois groups. I have also included extra motivating examples and modified the exercises. Known misprints have been corrected, but since this edition has been completely reset there will no doubt be some new ones to tax the reader’s ingenuity (and patience). The historical section has been modified in the light of new findings, and the publisher has kindly permitted me to do what I wanted to do in the first edition, namely, include photographs from Galois’s manuscripts, and other historical illustrations. Some of the mathematical proofs have been changed to improve their clarity, and in a few cases their correctness. Some material that I now consider superfluous has been deleted. I have tried to preserve the informal style of the original, which for many people was the book’s greatest virtue.

The new version has benefited from advice from several quarters. Lists of typographical and mathematical errors have been sent to me by Stephen Barber, Owen Brison, Bob Coates, Philip Higgins, David Holden, Frans Oort, Miles Reid, and C. F. Wright. The Open University used the first edition as the basis for course M333, and several members of its Mathematics Department have passed on to me the lessons that were learned as a result. I record for posterity my favourite example of OU wit, occasioned by a mistake in the index: “226: Stéphanie D. xix.” Should refer to page xxi (the course of true love never does run smooth, nor does it get indexed correctly).

I am grateful to them, and to their students, who acted as unwitting guinea pigs; take heart, for your squeaks have not gone unheeded.

Ian Stewart
Preface to the Third Edition

Galois Theory was the first textbook I ever wrote, although it was my third book, following a set of research-level lecture notes and a puzzle book for children. When I wrote it, I was an algebraist, and a closet Bourbakiste to boot; that is, I followed the fashion of the time which favoured generality and abstraction. For the uninitiated, Nicolas Bourbaki is the pseudonym of a group of mathematicians — mostly French, mostly young — who tidied up the mathematics of the mid-20th century in a lengthy series of books. Their guiding principle was never to prove a theorem if it could be deduced as a special case of a more general theorem. To study planar geometry, work in \( n \) dimensions and then let \( n = 2 \).

Fashions change, and nowadays the presentation of mathematics has veered back toward specific examples and a preference for ideas that are more concrete, more down-to-earth. Though what counts as concrete today would have astonished the mathematicians of the 19th century to whom the general polynomial over the complex numbers was the height of abstraction, to us it is a single concrete example.

As I write, Galois Theory has been in print for 30 years. With a lick of paint and a few running repairs, there is no great reason why it could not go on largely unchanged for another 30 years. “If it ain’t broke, don’t fix it.” But I have convinced myself that psychologically it is broke, even if its logical mechanism is as bright and shiny as ever. In short, the time has come to bring the mathematical setting into line with the changes that have taken place in undergraduate education since 1973. For this reason, the story now starts with polynomials over the complex numbers, and the central quest is to understand when such polynomials have solutions that can be expressed by radicals — algebraic expressions involving nothing more sophisticated than \( n \)th roots.

Only after this tale is complete is any serious attempt made to generalize the theory to arbitrary fields, and to exploit the language and thought-patterns of rings, ideals, and modules. There is nothing wrong with abstraction and generality — they are still cornerstones of the mathematical enterprise. But “abstract” is a verb as well as an adjective: general ideas should be abstracted from something, not conjured from thin air. Abstraction in this sense is highly non-Bourbakiste, best summed up by the counter-slogan “let \( 2 = n \).” To do that we have to start with case 2, and fight our way through it using anything that comes to hand, however clumsy, before refining our methods into an elegant but ethereal technique which — without such preparation — lets us prove case \( n \) without having any idea of what the proof does, how it works, or where it came from.

It was with some trepidation that I undertook to fix my non-broke book. The process turned out to be rather like trying to reassemble a jigsaw puzzle to create a different
picture. Many pieces had to be trimmed or dumped in the wastebasket, many new pieces had to be cut, discarded pieces had to be rescued and reinserted. Eventually order re-emerged from the chaos — or so I believe.

Along the way I made one change that may raise a few eyebrows. I have spent much of my career telling students that written mathematics should have punctuation as well as symbols. If a symbol or a formula would be followed by a comma if it were replaced by a word or phrase, then it should be followed by a comma; however strange the formula then looks.

I still think that punctuation is essential for formulas in the main body of the text. If the formula is $t^2 + 1$, say, then it should have its terminating comma. But I have come to the conclusion that eliminating visual junk from the printed page is more important than punctuatory pedantry, so that when the same formula is displayed, for example

$$t^2 + 1$$

then it looks silly if the comma is included, like this,

$$t^2 + 1,$$

and everything is much cleaner and less ambiguous without punctuation.

Purists will hate this, though many of them would not have noticed had I not pointed it out here. Until recently, I would have agreed. But I think it is time we accepted that the act of displaying a formula equips it with implicit (invisible) punctuation. This is the 21st century, and typography has moved on.

Other things have also moved on, and instant gratification is one of them. Modern audiences want to see some payoff today, if not last week. So I have placed the more accessible applications, such as the Three Geometric Problems of Antiquity, impossible geometric constructions, as early as possible. The price of doing this is that other material is necessarily delayed, and elegance is occasionally sacrificed for the sake of transparency.

I have preserved and slightly extended what was undoubtedly the most popular feature of the book, a wealth of historical anecdote and storytelling, with the romantic tale of Évariste Galois and his fatal duel as its centrepiece. "Pistols at 25 paces!" Bang! Even though the tale has been over-romanticized by many writers, as Rothman (1982, Internet) has convincingly demonstrated, the true story retains elements of high drama. I have also added some of the more technical history, such as Vandermonde's analysis of 11th roots of unity, to aid motivation. I have rearranged the mathematics to put the concrete before the abstract, but I have not omitted anything of substance. I have invented new — or, at least, barely shop-soiled — proofs for old theorems when I felt that the traditional proofs were obscure or needlessly indirect. And I have revived some classical topics, such as the nontrivial expression of roots of unity by radicals, having felt for 30 years that $\sqrt[3]{1}$ is cheating.

The climax of the book remains the proof that the quintic equation cannot be solved by radicals. In fact, you will now be subjected to four proofs, of varying generality. There is a short, snappy proof that the general polynomial equation of degree $n \geq 5$
cannot be solved by radicals that are rational functions of the coefficients. An optional section proving the Theorem on Natural Irrationalities, which was the big advance made by Abel in 1824, removes this restriction, and so provides the second proof. Lagrange came within a whisker of proving all of the above in 1770–1771, and Ruffini probably did prove it in 1799, but with the restriction to radicals that are rational functions of the coefficients. He seems to have thought that he had proved something stronger, which confused the issue. The proof given here has the merit of making the role of field automorphisms and the symmetric and alternating groups very clear, with hardly any fuss, and it could profitably be included in any elementary group theory course as an application of permutations and quotient groups. Proof 4 is a longer, abstract proof of the same fact, and this time the assumption that the radicals can be expressed as rational functions of the coefficients is irrelevant to the proof. In between is the third proof, which shows that a specific quintic equation, \( x^5 - 6x + 3 = 0 \), cannot be solved by radicals. This is the strongest statement of the four, and by far the most convincing; it takes the full-blooded Galois Theory to prove it.

The sole remaining tasks in this preface are to thank Chapman and Hall/CRC Press for badgering me into preparing a revised edition and persisting for several years until I caved in, and for putting the whole book into \LaTeX{} so that there was a faint chance that I might complete the task. And, as always, to thank careful readers, who for 30 years have sent in comments, lists of mistakes, and suggestions for new material. Two in particular deserve special mention. George Bergman suggested many improvements to the mathematical proofs, as well as pointing out typographical errors. Tom Brissenden sent a large file of English translations of documents related to Galois. Both have had a significant influence on this edition.

Historical Introduction

Mathematics has a rich history, going back at least 5000 years. Very few subjects still make use of ideas that are as old as that, but in mathematics, important discoveries have lasting value. The latest research almost certainly makes use of theorems that were published last year, but it may also use results first discovered by Archimedes, or by some unknown Babylonian mathematician, astronomer, or priest. For example, ever since Archimedes proved (around 250 BC) that the volume of a sphere is what we would now write as $\frac{4}{3}\pi r^3$, that discovery has been available to any mathematician whose research involves spheres. Although there are revolutions in mathematics, they are usually changes of viewpoint or philosophy; earlier results do not change — although the hypotheses needed to prove them may. In fact, there is a word in mathematics for previous results that are later changed: they are called “mistakes.”

The history of Galois theory is unusually interesting. It certainly goes back to 1600 BC, where among the mud-brick buildings of exotic Babylon, some priest or mathematician worked out how to solve a quadratic equation, and they or their students inscribed it in cuneiform on a clay tablet. Some such tablets survive to this day, along with others ranging from tax accounts to observations of the motion of the planet Jupiter, Figure 1.

Adding to this rich historical brew, the problems that Galois theory solves have an intrinsic fascination — squaring the circle, duplicating the cube, trisecting the angle, constructing the regular 17-sided polygon, solving the quintic equation. If the hairs on your neck do not prickle at the very mention of these age-old puzzles, you need to have your mathematical sensitivities sharpened.

If those were not enough, Galois himself was a colourful and tragic figure — a youthful genius, one of the thirty or so greatest mathematicians who have ever lived, but also a political revolutionary during one of the most turbulent periods in the history of France. At the age of 20 he was killed in a duel, ostensibly over a woman and quite possibly with a close friend, and his work was virtually lost to the world; only some smart thinking by Joseph Liouville rescued it. Galois’s story is one of the most memorable among the lives of the great mathematicians, even when the more excessive exaggerations and myths are excised.

Our tale, therefore, has two heroes: a mathematical one, the humble polynomial equation, and a human one, the tragic genius. We take them in turn.
Polynomial Equations

A Babylonian clay tablet from about 1600 BC poses arithmetrical problems that reduce to the solution of quadratic equations (Midonick, 1965, p. 48). The tablet also provides firm evidence that the Babylonians possessed general methods for solving quadratics, although they had no algebraic notation with which to express their solution. Babylonian notation for numbers was in base 60, so that (when transcribed into modern form) the symbols $7,4;3,11$ denote the number $7 \times 60^2 + 4 \times 60 + 3 \times 60^{-1} + 11 \times 60^{-2} = 25440\frac{191}{3600}$. In 1930 the historian of science Otto Neugebauer announced that some of the most ancient Babylonian problem tablets contained methods for solving quadratics. For instance, one tablet contains this problem: find the side of a square given that the area minus the side is 14.30. Bearing in
mind that 14,30 = 870 in decimal notation, we can formulate this problem as the quadratic equation

\[ x^2 - x = 870 \]

The Babylonian solution reads:

Take half of 1, which is 0;30, and multiply 0;30 by 0;30, which is 0;15. Add this to 14,30 to get 14,30;15. This is the square of 29;30. Now add 0;30 to 29;30. The result is 30, the side of the square.

Although this description applies to one specific equation, it is laid out so that similar reasoning can be applied in greater generality, and this was clearly the Babylonian scribe's intention. The method is the familiar procedure of completing the square, which nowadays leads to the usual formula for the solution of a quadratic. See Joseph (2000) for more on Babylonian mathematics.

The ancient Greeks in effect solved quadratics by geometric constructions, but there is no sign of an algebraic formulation until at least AD 100 (Bourbaki, 1969, p. 92). The Greeks also possessed methods for solving cubic equations that involved the points of intersection of conics. Again, algebraic solutions of the cubic were unknown, and in 1494 Luca Pacioli ended his *Summa di Arithmetica* (Figure 2) with the remark that (in his archaic notation) the solution of the equations \( x^3 + mx = n \) and \( x^3 + n = mx \) was as impossible at the existing state of knowledge as squaring the circle.

This state of ignorance was soon to change, as new knowledge from the Middle and Far East swept across Europe, and the Christian Church's stranglehold on intellectual innovation began to weaken. The Renaissance mathematicians at Bologna discovered that the solution of the cubic can be reduced to that of three basic types: \( x^3 + px = q \), \( x^3 = px + q \), and \( x^3 + q = px \). They were forced to distinguish these cases because they did not recognize the existence of negative numbers. It is thought, on good authority (Bortolotti, 1925), that Scipio del Ferro solved all three types; he certainly passed on his method for one type to a student, Antonio Fior. News of the solution leaked out, and others were encouraged to try their hand. Solutions for the cubic equation were rediscovered by Niccolo Fontana (nicknamed Tartaglia, "The Stammerer," Figure 3) in 1535.

One of the more charming customs of the period was the public mathematical contest, in which mathematicians engaged in mental duels using computational expertise as their weapons. Mathematics was a kind of performance art. Fontana demonstrated his methods in a public competition with Fior, but refused to reveal the details. Finally, he was persuaded to tell them to the physician Girolamo Cardano, having first sworn him to secrecy. Cardano, the "gambling scholar," was a mixture of genius and rogue, and when his *Ars Magna* (Figure 4) appeared in 1545, it contained a complete discussion of Fontana's solution. Although Cardano claimed motives of the highest order (see the modern translation of his *The Book of My Life*, 1931), and fully acknowledged Fontana as the discoverer, Fontana was justifiably annoyed. In the ensuing wrangle, the history of the discovery became public knowledge.
Figure 2: A page from Pacioli’s *Summa di Arithmetica*.

The *Ars Magna* also contained a method, due to Ludovico Ferrari, for solving the quartic equation by reducing it to a cubic. Ferrari was one of Cardano’s students, so presumably he had given permission for his work to be published… or perhaps a student’s permission was not needed. All the formulas discovered had one striking property, which can be illustrated by Fontana’s solution $x^3 + px = q$:

$$x = \sqrt[3]{\frac{q}{2} + \sqrt{\frac{p^3}{27} + \frac{q^2}{4}}} + 3\sqrt[3]{\frac{q}{2} - \sqrt{\frac{p^3}{27} + \frac{q^2}{4}}}$$

This expression, usually called Cardano’s formula because he was the first to publish it, is built up from the coefficients $p$ and $q$ by repeated addition, subtraction, multiplication, division, and — crucially — extraction of roots. Such expressions became known as radicals.

Since all equations of degree $\leq 4$ were now solved by radicals, it was natural to ask how to solve the quintic equation by radicals. Ehrenfried Walter von Tschirnhaus
Figure 3: Niccolo Fontana (Tartaglia), who discovered how to solve cubic equations.

claimed a solution in 1683, but Gottfried Wilhelm Leibniz correctly pointed out that it was fallacious. Leonhard Euler failed to solve the quintic, but found new methods for the quartic, as did Etienne Bézout in 1765. Joseph-Louis Lagrange took a major step forward in his magnum opus Réflexions sur la Résolution Algébrique des Équations of 1770–1771, when he unified the separate tricks used for the equations of degree \( \leq 4 \). He showed that they all depend on finding functions of the roots of the equation that are unchanged by certain permutations of those roots, and he showed that this approach fails when it is tried on the quintic. It did not prove that the quintic is insoluble by radicals, because other methods might succeed where this particular one had not. But the failure of such a general method was, to say the least, suspicious.

A general feeling that the quintic could not be solved by radicals was now in the air. In 1799 Paolo Ruffini published a two-volume book Teoria Generale delle Equazioni whose 516 pages constituted an attempt to prove the insolubility of the quintic. Tignol (1988) describes the history, saying that “Ruffini’s proof was received with scepticism in the mathematical community.” The length and complexity of the proof seem to have been the main stumbling block; at any rate, no coherent criticisms emerged. In 1810 Ruffini had another go, submitting a long paper about quintics to the French Academy:
the paper was rejected on the grounds that the referees could not spare the time to check it. In 1813 he published yet another version of his impossibility proof. The paper appeared in an obscure journal, with several gaps in the proof (Bourbaki, 1969, p. 103). The most significant omission was to assume without proof that all radicals involved must be rational functions of the roots (see Section 8.7). Nonetheless, Ruffini had made a big step forward, even though it was not appreciated at the time.

As far as the mathematical community of the period was concerned, the question was finally settled by Niels Henrik Abel in 1824, who proved conclusively that the general quintic equation is insoluble by radicals. In particular, he filled in the big gap in Ruffini’s work. But Abel’s proof was unnecessarily lengthy and contained a minor error, which, fortunately, did not invalidate the method. In 1879 Leopold Kronecker published a simple, rigorous proof that tidied up Abel’s ideas.
The "general" quintic is therefore insoluble by radicals, but special quintic equations might still be soluble. Some are; see Section 1.4. Indeed, for all that Abel's methods could prove, every particular quintic equation might be soluble, with a special formula for each equation. So a new problem now arose: to decide whether any particular equation can be solved by radicals. Abel was working on this question just before he died of tuberculosis in 1829.

In 1832 a young Frenchman, Évariste Galois, was killed in a duel. He had for some time sought recognition for his mathematical theories, submitting three memoirs to the Academy of Sciences in Paris. They were all rejected, and his work appeared to be lost to the mathematical world. Then, on 4 July 1843, Liouville addressed the Academy. He opened with these words:

I hope to interest the Academy in announcing that among the papers of Évariste Galois I have found a solution, as precise as it is profound, of this beautiful problem: whether or not there exists a solution by radicals...

The Life of Galois

The most accessible account of Galois's troubled life, Bell (1965), is also one of the less reliable, and in particular seriously distorts the events surrounding his death. The best source I know is Rothman (1982) and its more recent revision on the Web (Rothman, Internet). The account given here is by no means exhaustive, and Rothman’s website is the best place to start from if you want to know more.

Évariste Galois (Figure 5) was born at Bourg-la-REine near Paris on 25 October 1811. His father, Nicolas-Gabriel Galois, was a Republican (Kollros, 1949); that is, he favoured the abolition of the monarchy. He was head of the village liberal party, and after the return to the throne of Louis XVIII in 1814, Nicolas became town mayor. Évariste's mother, Adelaide-Marie (née Demante), was the daughter of a jurisconsult, a legal expert who gives opinions about cases brought before him. She was a fluent reader of Latin, thanks to a solid education in religion and the classics.

For the first 12 years of his life, Galois was educated by his mother, who passed on to him a thorough grounding in the classics, and his childhood appears to have been a happy one. At the age of 10 he was offered a place at the College of Reims, but his mother preferred to keep him at home. In October 1823 he entered a preparatory school, the College de Louis-le-Grand. There he got his first taste of revolutionary politics: during his first term the students rebelled and refused to chant in chapel. He also witnessed heavy-handed retribution, for a hundred of the students were expelled for their disobedience.

Galois performed well during his first 2 years at school, obtaining first prize in Latin, but then boredom set in. He was made to repeat the next year's classes, but predictably this just made things worse. During this period, probably as refuge from the tedium, Galois began to take a serious interest in mathematics. He came across a copy of Adrien-Marie Legendre's Éléments de Géométrie, a classic text which broke with the Euclidean tradition of school geometry. According to Bell (1965) he read it "like a novel," and mastered it in one reading — but Bell is prone to exaggeration
Figure 5: Portrait of Évariste Galois drawn from memory by his brother Alfred, 1848.

Whatever the truth here, the school algebra texts certainly could not compete with Legendre’s masterpiece as far as Galois was concerned, and he turned instead to the original memoirs of Lagrange and Abel. At the age of 15 he was reading material intended only for professional mathematicians. But his classwork remained uninspired, and he seems to have lost all interest in it. His rhetoric teachers were particularly unimpressed by his attitude, and he was thought to be affecting ambition and originality, and even his own family considered him rather strange at that time.

Galois did make life very difficult for himself. For a start, he was an untidy worker, as can be seen from some of his manuscripts (Bourgne and Azra, 1962). Worse, he tended to work in his head, committing only the results of his deliberations to paper. His mathematics teacher, Vernier, begged him to work systematically, no doubt so that ordinary mortals could follow his reasoning, but Galois ignored this advice. Without adequate preparation and a year early, he took the competitive examination for entrance to the École Polytechnique. A pass would have ensured a successful
mathematical career, for the Polytechnique was the breeding ground of French mathematics. Of course, he failed. Two decades later, Olyer Terquem (editor of the journal *Nouvelles Annales des Mathématiques*) advanced the following explanation: “A candidate of superior intelligence is lost with an examiner of inferior intelligence. Because they do not understand me, I am a barbarian...” To be fair to the examiner, communication skills are an important ingredient of success, as well as natural ability. We might counter Terquem with, “Because I do not take account of their inferior intelligence, I am an idiot.” But Galois was too young and impetuous to see it that way.

In 1828 Galois enrolled in an advanced mathematics course offered by Louis-Paul-Émile Richard, who recognized his ability and was very sympathetic toward him. He was of the opinion that Galois should be admitted to the Polytechnique without examination — probably because he recognized the dangerous combination of high talent and poor examination technique. If this opinion was ever communicated to the Polytechnique, it fell on deaf ears.

The following year saw the publication of Galois’s first research paper (Galois, 1897) on continued fractions; though competent, it held no hint of genius. Meanwhile, Galois had been making fundamental discoveries in the theory of polynomial equations, and he submitted some of his results to the Academy of Sciences. The referee was Augustin-Louis Cauchy, who had already published work on the behaviour of functions under permutation of the variables, a central theme in Galois’s theory.

As Rothman (Internet) says, “We now encounter a major myth.” Many sources state that Cauchy lost the manuscript, or even deliberately threw it away, either to conceal its contents, or because he considered it worthless. But René Taton (1971) found a letter written by Cauchy in the archives of the Academy. Dated 18 January 1830, it reads in part:

I was supposed to present today to the Academy first a report on the work of the young Galois [spelling was not consistent in those days] and second a memoir on the analytic determination of primitive roots [by Cauchy]... Am indisposed at home. I regret not being able to attend today’s session, and I would like you to schedule me for the following session for the two indicated subjects.

So Cauchy still had the manuscript in his possession, 6 months after Galois had submitted it. Moreover, he found the work sufficiently interesting to want to draw it to the Academy’s attention. However, at the next session of the Academy, on 25 January, Cauchy presented only his own paper. What had happened to the paper by Galois?

Taton suggests that Cauchy was actually very impressed by Galois’s research, so much so that he advised Galois to prepare a new (no doubt improved) version, and to submit it for the Grand Prize in Mathematics, the pinnacle of mathematical honour, which had a March 1 deadline. There is no direct evidence for this assertion, but the circumstantial evidence is quite convincing. We do know that Galois made such a submission in February. The following year the journal *Le Globe* published an appeal for Galois’s acquittal during his trial for allegedly threatening the king’s life (see below):
Last year before March 1, M. Galois gave to the secretary of the Institute a memoir on the solution of numerical equations. This memoir should have been entered in the competition for the Grand Prize in Mathematics. It deserved the prize, for it could resolve some difficulties that Lagrange had failed to do. Cauchy had conferred the highest praise on the author about this subject. And what happened? The memoir is lost and the prize is given without the participation of the young savant.

Rothman points out that Cauchy fled France in September 1830, so the article is unlikely to have been based on Cauchy’s own statements. Le Globe was a journal of the Saint-Simonian organization, a neo-Christian socialist movement founded by the Comte de Sainte-Simone. When Galois left jail, his closest friend Auguste Chevalier invited him to join a Saint-Simonian commune founded by Prosper Enfantin. Chevalier was a very active member and an established journalist. It is plausible that Chevalier wrote the article, in which case the original source would have been Galois himself. If so, Galois knew that Cauchy had been impressed by the work.

The same year held two major disasters. On 2 July 1829 Galois’s father committed suicide after a bitter political dispute in which the village priest forged Nicolas’s signature on malicious epigrams aimed at his own relatives. It could not have happened at a worse time, for a few days later Galois again sat for entrance to the Polytechnique — his final chance. There is a legend (Bell, 1965; Dupuy, 1896) that he lost his temper and threw an eraser into the examiner’s face, but according to Bertrand (1899) this tradition is false. Apparently the examiner, Dinet, asked Galois some questions about logarithms.

In one version of the story, Galois made some statements about logarithmic series, Dinet asked for proofs, and Galois refused on the grounds that the answer was completely obvious. A variant asserts that Dinet asked Galois to outline the theory of “arithmetical logarithms.” Galois informed him, no doubt with characteristic bluntness, that there were no arithmetical logarithms. Dinet failed him.

Was Galois right, though? It depends on what Dinet had in mind. The phrase “arithmetical logarithms” is not necessarily meaningless. In 1801 Carl Friedrich Gauss had published his epic Disquisitiones Arithmeticae, which laid the foundations of number theory for future generations of mathematicians. Ironically, Gauss had sent it to the French Academy in 1800, and it was rejected. Nice track record. In the Disquisitiones, Gauss developed the notion of a primitive root modulo a prime. If \( g \) is a primitive root \( (\text{mod } p) \) then every nonzero element \( m (\text{mod } p) \) can be written as a power \( m = g^{a(m)} \). Then \( a(mn) = a(m) + a(n) \), so \( a(m) \) is analogous to \( \log m \). Gauss called \( a(m) \) the index of \( m \) to base \( g \), and Article 58 of his book begins by stating, “Theorems pertaining to indices are completely analogous to those that refer to logarithms.” So if this is what Dinet was asking about, any properly prepared candidate should have recognised it, and known about it.

Because he had expected to be admitted to the Polytechnique, Galois had not studied for his final examinations. Now faced with the prospect of the École Normale, then called the École Préparatoire, which at that time was far less prestigious than the
Polynomial Equations

Polytechnique, he belatedly prepared for them. His performance in mathematics and physics was excellent, in literature less so; he obtained both the Bachelor of Science and Bachelor of Letters on 29 December 1829.

Possibly following Cauchy's recommendation, in February 1830 Galois presented a new version of his research to the Academy of Sciences in competition for the Grand Prize in Mathematics. The manuscript reached the secretary, Joseph Fourier, who took it home for perusal. But he died before reading it, and the manuscript could not be found among his papers. It may not have been Fourier who lost it, however; the Grand Prize committee had three other members: Legendre, Sylvestre-François Lacroix, and Louis Poinsot.

If the article in *Le Globe* is to be believed, no lesser a light than Cauchy had considered Galois's manuscript to have been worthy of the prize. The loss was probably an accident, but according to Dupuy (1896), Galois was convinced that the repeated losses of his papers were not just bad luck. He saw them as the inevitable effect of a society in which genius was condemned to an eternal denial of justice in favour of mediocrity, and he blamed the politically oppressive Bourbon regime. He may well have had a point, accident or not.

At that time, France was in political turmoil. King Charles X succeeded Louis XVIII in 1824. In 1827 the liberal opposition made electoral gains; in 1830 more elections were held, giving the opposition a majority. Charles, faced with abdication, attempted a coup d'État. On 25 July he issued his notorious Ordonnances suppressing the freedom of the press. The populace was in no mood to tolerate such repression, and revolted. The uprising lasted 3 days, after which a compromise the Duke of Orléans, Louis-Philippe, was made king. During these 3 days, while the students of the Polytechnique were making history in the streets, Galois and his fellow students were locked in by Guigniault, Director of the École Normale. Galois was incensed, and subsequently wrote a blistering attack on the Director in the *Gazette des Écoles*, signing the letter with his full name. An excerpt (the letter was published in December) reveals the general tone:

Gentlemen:

The letter which M. Guigniault placed in the Lycée yesterday, on the account of one of the articles in your journal, seemed to me most improper. I had thought that you would welcome eagerly any way of exposing this man.

Here are the facts which can be vouched for by forty-six students.

On the morning of July 28, when several students of the École Normale wanted to join in the struggle, M. Guigniault told them, twice, that he had the power to call the police to restore order in the school. The police on the 28th of July!

The same day, M. Guigniault told us with his usual pedantry: “There are many brave men fighting on both sides. If I were a soldier, I would not know what to decide. Which to sacrifice, liberty or LEGITIMACY?”

There is the man who the next day covered his hat with an enormous tricolor cockade. There are our liberal doctrines!
The editor removed the signature, the Director was not amused, and Galois was expelled because of his "anonymous" letter (Dalmas, 1956).

Galois promptly joined the Artillery of the National Guard, a branch of the militia composed almost entirely of Republicans. On 21 December 1830 the Artillery of the National Guard, almost certainly including Galois, was stationed near the Louvre, awaiting the verdict of the trial of four ex-ministers. The public wanted these functionaries executed, and the Artillery was planning to rebel if they received only life sentences. Just before the verdict was announced, the Louvre was surrounded by the full National Guard, plus other troops who were far more trustworthy. When the verdict of a jail sentence was heralded by a cannon shot, the revolt failed to materialize. On 31 December, the Artillery of the National Guard was abolished by the king, because it constituted a serious security threat.

Galois was now faced with the urgent problem of making a living. On 13 January 1831 he tried to set up as a private teacher of mathematics, offering a course in advanced algebra. Forty students enrolled, but the class soon petered out, probably because Galois was too involved in politics. On 17 January he submitted a third version of his memoir to the Academy: *On the Conditions of Solvability of Equations by Radicals*. Cauchy was no longer in Paris, so Siméon Poisson and Lacroix were appointed referees. After 2 months Galois had heard no word from them. He wrote to the President of the Academy, asking what was happening. He received no reply.

During the spring of 1831, Galois's behaviour became more and more extreme, verging on the paranoid. On April 18 Sophie Germain (one of the few women mathematicians of the time) who studied with Gauss, wrote to Guillaume Libri about Galois's misfortunes: "They say he will go completely mad, and I fear this is true." See Henry (1879). Also in April, 19 members of the Artillery of the National Guard, arrested after the events at the Louvre, were put on trial charged with attempting to overthrow the government; the jury acquitted them. On 9 May a banquet was held to celebrate their acquittal; about 200 Republicans were present, all extremely hostile to the government of Louis-Philippe. The proceedings became more and more riotous, and Galois was seen with a glass in one hand and a dagger in the other. His companions allegedly interpreted this as a threat to the king's life, applauded mightily, and ended up dancing and shouting in the street.

The next day, Galois was arrested. At his subsequent trial, he admitted everything, but claimed that the toast proposed was actually, "To Louis-Philippe, *if he turns traitor*," and that the uproar had drowned the last phrase. But he also made it crystal clear that he expected Louis-Philippe to do just that. Nevertheless, the jury acquitted him, probably because of his youth, and he was freed on 15 June.

On 4 July he heard the fate of his memoir. Poisson declared it "incomprehensible." The report (reprinted in full in Taton, 1947) ended as follows:

We have made every effort to understand Galois's proof. His reasoning is not sufficiently clear, sufficiently developed, for us to judge its correctness, and we can give no idea of it in this report. The author announces that the proposition which is the special object of this memoir is part of a general theory susceptible of many applications. Perhaps it will
transpire that the different parts of a theory are mutually clarifying, are easier to grasp together rather than in isolation. We would then suggest that the author should publish the whole of his work in order to form a definitive opinion. But in the state which the part he has submitted to the Academy now is, we cannot propose to give it approval.

The report may well have been entirely fair. Tignol (1988) points out that Galois’s entry “did not yield any workable criterion to determine whether an equation is solvable by radicals.” The referees’ report was explicit:

[The memoir] does not contain, as [its] title promised, the condition of solubility of equations by radicals; indeed, assuming as true M. Galois’s proposition, one could not derive from it any good way of deciding whether a given equation of prime degree is soluble or not by radicals, since one would first have to verify whether this equation is irreducible and next whether any of its roots can be expressed as a rational fraction of two others.

The final sentence here refers to a beautiful criterion for solubility by radicals of equations of prime degree that was the climax of Galois’s memoir. It is indeed unclear how it can be applied to any specific equation. Tignol says, “Galois’s theory did not correspond to what was expected, it was too novel to be readily accepted.” What the referees wanted was some kind of condition on the coefficients that determined solubility; what Galois gave them was a condition on the roots. As Tignol explains, the referees’ expectation was unreasonable; no simple criterion based on the coefficients has ever been found, nor is one remotely likely.

On 14 July, Bastille Day, Galois and his friend Ernest Duchâtelet were at the head of a Republican demonstration. Galois was wearing the uniform of the disbanded Artillery, and carrying a knife, several pistols, and a loaded rifle. It was illegal to wear the uniform, and even more so to be armed. Both men were arrested on the Pont-Neuf, and Galois was charged with the lesser offence of illegally wearing a uniform. They were sent to the jail at Sainte-Pélagie to await trial. While in jail, Duchâtelet drew a picture on the wall of his cell showing the king’s head, labelled as such, lying next to a guillotine. This presumably did not help their cause. Duchâtelet was tried first; then it was Galois’s turn. On 23 October he was tried and convicted, and his appeal was turned down on 3 December. By this time he had spent more than 4 months in jail. Now he was sentenced to 6 months there. He worked for a while on his mathematics (Figure 6); then in the cholera epidemic of 1832 he was transferred to a hospital. Soon he was put on parole.

Along with his freedom he experienced his first and only love affair, with a certain Mlle. Stéphanie D. From this point on, the history becomes very complicated and conjectural. Until recently, the young lady’s surname was unknown, adding to the romantic image of the femme fatale. The full name appears in one of Galois’s manuscripts, but the surname has been obliterated, no doubt by Galois. Some forensic work by Carlos Infanzonuzzi (1968), who examined the manuscript more carefully than his predecessors had, revealed the lady as Stéphanie-Félicie Poterin du Motel, the entirely respectable
daughter of Jean-Louis Auguste Poterin du Motel. Jean-Louis was resident physician at the Sieur Faultrier, where Galois spent the last few months of his life.

There is much mystery surrounding this interlude, which has a crucial bearing on subsequent events. Apparently Galois was rejected, and took it very badly. On 25 May he wrote to Chevalier: “How can I console myself when in one month I have exhausted the greatest source of happiness a man can have?” On the back of one of his papers he made fragmentary copies of two letters from Stéphanie (Tannery, 1908; Bourgne and Azra, 1962). One begins “Please let us break up this affair” and continues “… and do not think about those things which did not exist and which never would have existed.” The other contains the sentences: “I have followed your advice and I have thought over what... has... happened... In any case, Sir, be assured there never would have been more. You’re assuming wrongly and your regrets have no foundation.”

Not long afterward, Galois was challenged to a duel, ostensibly because of his advances toward the young lady. Again, the circumstances are veiled in mystery, though Rothman (1982, Internet) has lifted a corner of the veil. One school of thought (Bell, 1965; Kollros, 1949) asserts that Galois’s infatuation with Mlle. du Motel was used by his political opponents, who found it the perfect excuse to eliminate their
Figure 7: Doodles left on the table before departing for the fatal duel. Une femme, with the second word scribbled out, can be seen near the lower left corner.

enemy on a trumped-up affair of honour. There are even suggestions that Galois was, in effect, assassinated by a police spy.

But in his Mémoires, Alexandre Dumas says that Galois was killed by Pescheux D’Herbinville, a fellow Republican. See Dumas (1967). Dumas described D’Herbinville as “a charming young man who made silk-paper cartridges which he would tie up with silk ribbons” (the objects concerned seem to have been an early form of cracker of the kind now familiar at Christmas). He was one of the 19 Republicans acquitted on charges of conspiring to overthrow the government, and something of a hero with the peasantry. D’Herbinville was certainly not a spy for the police; all such men were named in 1848 when Caussidière became chief of police. Dalmas (1956) cites evidence from the police report suggesting that the other duellist was one of Galois’s revolutionary comrades, and the duel was exactly what it appeared to be. This theory is largely borne out by Galois’s own words on the matter (Bourgne and Azra, 1962) (Figure 7).

I beg patriots and my friends not to reproach me for dying otherwise than for my country. I dic the victim of an infamous coquette. It is in a miserable brawl that my life is extinguished. Oh! why die for so trivial a thing, for something so despicable! . . . Pardon for those who have killed me, they are of good faith.
Figure 8: “I have no time” (je n’ai pas le temps) above deleted paragraph in lower left corner. But consider the context.

It does appear that Stéphanie was at least a proximate cause of the duel, but very little else is clear.

On 29 May, the eve of the duel, Galois wrote a famous letter to his friend Auguste Chevalier, outlining his mathematical discoveries. This letter was eventually published by Chevalier in the *Revue Enzytopédique*. In it, Galois sketched the connection between groups and polynomial equations, stating that an equation is soluble by radicals provided its group is soluble. But he also mentioned many other ideas about elliptic functions and the integration of algebraic functions, and other things too cryptic to be identifiable.

The scrawled comment, “I have no time,” in the margins (Figure 8) has given rise to another myth: that Galois spent the night before the duel frantically writing out his
mathematical discoveries. However, that phrase has next to it "(Author's note)," which hardly fits such a picture; moreover, the letter was an explanatory accompaniment to Galois's rejected third manuscript, complete with a marginal note added by Poisson (Figure 9).

The duel was with pistols. The postmortem report (Dupuy, 1896) states that they were fired at 25 paces, but the truth may have been even nastier. Dalmas reprints an article from the 4 June 1832 issue of Le Precursor, which reports:

Paris, 1 June — A deplorable duel yesterday has deprived the exact sciences of a young man who gave the highest expectations, but whose celebrated precocity was lately overshadowed by his political activities. The young Évariste Galois... was fighting with one of his old friends, a young man like himself, like himself a member of the Society of Friends of the People, and who was known to have figured equally in a political trial. It is said that love was the cause of the combat. The pistol was the chosen weapon of the adversaries, but because of their old friendship they could not bear to look at one another and left the decision to blind fate.
At point-blank range they were each armed with a pistol and fired. Only one pistol was charged. Galois was pierced through and through by a ball from his opponent; he was taken to the hospital Cochin where he died in about two hours. His age was 22. L.D., his adversary, is a bit younger.

Who was L.D.? Does the initial “D” refer to d’Herbinville? Perhaps. “D” is acceptable because of the variable spelling of the period; the “L” may have been a mistake. The article is unreliable on details; it gets the date of the duel wrong, and also the day Galois died and his age. So the initial might also be wrong. Rothman has another theory, and a more convincing one. The person who best fits the description here is not d’Herbinville, but Duchâtelet, who was arrested with Galois on the Pont-Neuf. Bourgne and Azra (1962) give his Christian name as Ernest, but that might be wrong, or again the “L” may be wrong. To quote Rothman: “we arrive at a very consistent and believable picture of two old friends falling in love with the same girl and deciding the outcome by a gruesome version of Russian roulette.”
This theory is also consistent with a final horrific twist to the tale. Galois was hit in the stomach, a particularly serious wound that was almost always fatal. If indeed the duel was at point-blank range, this is no great surprise. If at 25 paces, he was unlucky.

He did not die 2 hours later, as *Le Precursor* says, but a day later on 31 May, of peritonitis; he refused the office of a priest. On 2 June 1832 he was buried in the common ditch at the cemetery of Montparnasse.

His letter to Chevalier ended with these words (Figure 10):

Ask Jacobi or Gauss publicly to give their opinion, not as to the truth, but as to the importance of these theorems. Later there will be, I hope, some people who will find it to their advantage to decipher all this mess...
Chapter 1

Classical Algebra

In the first part of this book, Chapters 1 to 15, we present a (fairly) modern version of Galois's ideas in the same setting that he used, namely, the complex numbers. Later, from Chapter 16 onward, we will generalize the setting, but the complex numbers have the advantages of being familiar and concrete. By restricting ourselves to complex numbers, we can focus on the main ideas that Galois introduced, without getting distracted by abstract nonsense.

A warning is in order. The decision to work over the complex numbers has its advantages in terms of accessibility of the material, but it sometimes makes the discussion seem clumsy by comparison to the elegance of an axiomatic approach. This is arguably a price worth paying, because this way we appreciate the abstract viewpoint when it makes its appearance, and we understand where it comes from.

We will assume familiarity with the basic theory of real and complex numbers, but to set the scene, we recall some of the concepts involved. We begin with a brief discussion of complex numbers. We introduce two important ideas; both relate to subsets of the complex numbers that are closed under the usual arithmetic operations. A subring of the complex numbers is a subset closed under addition, subtraction, and multiplication; a subfield is a subring that is also closed under division by any nonzero element. Both concepts were formalized by Richard Dedekind in 1871, though the ideas go back to Peter Gustav Lejeune-Dirichlet and Kronecker in the 1850s.

We then show that the historical sequence of extensions of the number system, from natural numbers to integers to rationals to reals to complex numbers, can with hindsight be interpreted as a quest to make more and more equations have solutions. We are thus led to the concept of a polynomial, which is central to Galois theory because it determines the type of equation that we wish to solve. And we appreciate that the existence of a solution depends on the kind of number we are permitting.

Throughout, we use the standard notation $\mathbb{N}, \mathbb{Z}, \mathbb{Q}, \mathbb{R}, \mathbb{C}$ for the sets (respectively) of natural numbers, integers, rationals, real numbers, and complex numbers. These systems are related as follows:

$$\mathbb{N} \subseteq \mathbb{Z} \subseteq \mathbb{Q} \subseteq \mathbb{R} \subseteq \mathbb{C}$$

and each $\subseteq$ symbol here hints at a lengthy historical process in which "new numbers" were proposed for mathematical reasons — usually against serious resistance on the grounds that although their novelty was not in dispute, they were not numbers and therefore did not exist.
1.1 Complex Numbers

A complex number has the form

\[ z = x + iy \]

where \( x, y \) are real numbers and \( i^2 = -1 \). Therefore, \( i = \sqrt{-1} \), in some sense.

The easiest way to define what we mean by \( \sqrt{-1} \) is to consider \( \mathbb{C} \) as the set \( \mathbb{R}^2 \) of all pairs of real numbers \((x, y)\), with algebraic operations

\[
\begin{align*}
(x_1, y_1) + (x_2, y_2) &= (x_1 + x_2, y_1 + y_2) \\
(x_1, y_1)(x_2, y_2) &= (x_1x_2 - y_1y_2, x_1y_2 + x_2y_1)
\end{align*}
\]

Then we identify \((x, 0)\) with the real number \( x \) to arrange that \( \mathbb{R} \subseteq \mathbb{C} \), and define \( i = (0, 1) \). In consequence, \((x, y)\) becomes identified with \( x + iy \). The formulas (1.1) imply that \( i^2 = (0, 1)(0, 1) = (-1, 0) \) which is identified with the real number \(-1\), so \( i \) is a square root of minus one. Observe that \((0, 1)\) is not of the form \((x, 0)\), so \( i \) is not real, which is as it should be, because \(-1\) has no real square root.

This approach seems to have been published first by the Irish mathematician William Rowan Hamilton in 1837, but in that year Gauss wrote to the geometer Wolfgang Bolyai that the same idea had occurred to him in 1831. This was probably true, because Gauss usually worked things out before anybody else did, but he set himself such high standards for publication that many of his more important ideas never saw print under his name. Gauss was somewhat conservative, and shied away from anything potentially controversial.

Once we see that complex numbers are just pairs of real numbers, the previously mysterious status of the imaginary number \( \sqrt{-1} \) becomes much more prosaic. In fact, to the modern eye it is the real numbers that are mysterious, because their rigorous definition involves analytic ideas such as sequences and convergence, which lead into deep philosophical waters and axiomatic set theory. In contrast, the step from \( \mathbb{R} \) to \( \mathbb{R}^2 \) is essentially trivial, except for the peculiarities of human psychology.

1.2 Subfields and Subrings of the Complex Numbers

For the first half of this book, we try to keep everything as concrete as possible — but not more so, as Albert Einstein is supposed to have said about keeping things simple. Abstract algebra courses usually introduce (at least) three basic types of algebraic structure defined by systems of axioms: groups, rings, and fields. Linear algebra adds a fourth: vector spaces. For the first half of this book, we steer clear of abstract rings and fields, but we do assume the basics of finite group theory and linear algebra.

Recall that a group is a set \( G \) equipped with an operation of multiplication written \((g, h) \mapsto gh\). If \( g, h \in G \) then \( gh \in G \). The associative law \((gh)k = g(hk)\) holds for
all $g, h, k \in G$. There is an identity $1 \in G$ such that $1g = g = g1$ for all $g \in G$. Finally, every $g \in G$ has an inverse $g^{-1} \in G$ such that $gg^{-1} = 1 = g^{-1}g$. The classic example here is the symmetric group $S_n$, consisting of all permutations of the set \{1, 2, \ldots, n\} under the operation of composition. We assume familiarity with these axioms, and with subgroups, isomorphisms, homomorphisms, normal subgroups, and quotient groups.

Rings are sets equipped with operations of addition, subtraction, and multiplication; fields also have a notion of division. The formal definitions were supplied by Heinrich Weber in 1893. The axioms specify the formal properties assumed for these operations, for example, the commutative law $ab = ba$ for multiplication. In the first part of this book, we do not assume familiarity with abstract rings and fields. Instead, we restrict attention to subrings and subfields of $\mathbb{C}$, or polynomials and rational functions over such subrings and subfields. Informally, we assume that the terms polynomial and rational expression (or rational function) are familiar, at least over $\mathbb{C}$, although for safety's sake we shall define them shortly when the discussion becomes more formal, and redefine them when we make the whole theory more abstract in the second part of the book. There were no formal concepts of “ring” or “field” in Galois's day, and precious little linear algebra; he had to invent groups for himself. So we are still permitting ourselves a more extensive conceptual toolkit than he had access to.

**Definition 1.1** A subring of $\mathbb{C}$ is a subset $R \subseteq \mathbb{C}$ such that $1 \in R$, and if $x, y \in R$, then $x + y$, $-x$, and $xy \in R$.

A subfield of $\mathbb{C}$ is a subring $K \subseteq \mathbb{C}$ with the additional property that if $x \in K$ and $x \neq 0$, then $x^{-1} \in K$.

It follows immediately that every subring of $\mathbb{C}$ contains $1 + (-1) = 0$, and is closed under the algebraic operations of addition, subtraction, and multiplication. A subfield of $\mathbb{C}$ has all of these properties, and is also closed under division by any nonzero element. Because $R$ and $K$ are subsets of $\mathbb{C}$, they inherit the usual rules for algebraic manipulation.

**Example 1.2**

1. The set of all $a + bi$, for $a, b \in \mathbb{Z}$, is a subring of $\mathbb{C}$, but not a subfield.

2. The set of all $a + bi$, for $a, b \in \mathbb{Q}$, is a subfield of $\mathbb{C}$.

3. The set of all polynomials in $\pi$, with integer coefficients, is a subring of $\mathbb{C}$, but not a subfield.

4. The set of all polynomials in $\pi$, with rational coefficients, is a subring of $\mathbb{C}$. By observing that $\pi$ satisfies no nontrivial polynomial equation with rational coefficients, as we prove in Theorem 5, it can be proved that this set is not a subfield.

5. The set of all rational expressions in $\pi$ with rational coefficients (that is, fractions $p(\pi)/q(\pi)$ where $p, q$ are polynomials over $\mathbb{Q}$ and $q(\pi) \neq 0$) is a subfield of $\mathbb{C}$. 
6. The set $2\mathbb{Z}$ of all even integers is not a subring of $\mathbb{C}$, because it does not contain 1. (For the initiated, when we say “subring” we assume that it is a ring with 1.)

7. The set of all $a + b\sqrt{2}$, for $a, b \in \mathbb{Q}$, is not a subring of $\mathbb{C}$ because it is not closed under multiplication. However, it is closed under addition and subtraction.

**Definition 1.3** Suppose that $K$ and $L$ are subfields of $\mathbb{C}$. An *isomorphism* between $K$ and $L$ is a map $\phi : K \to L$ such that

$$\phi(x + y) - \phi(x) + \phi(y) \quad \phi(x y) - \phi(x)\phi(y)$$

for all $x, y \in K$, where $\phi$ is one-to-one and onto.

It follows that $\phi(-x) = -\phi(x)$ and $\phi(x^{-1}) = (\phi(x))^{-1}$. If $\phi$ is one-to-one but not necessarily onto, it is a *monomorphism*. An isomorphism of $K$ with itself is called an *automorphism* of $K$.

**Example 1.4**

1. Complex conjugation $x + iy \mapsto x - iy$ is an automorphism of $\mathbb{C}$. Indeed, if we denote this map by $\alpha$, then:

$$\alpha((x + iy) + (u + iv)) = (x + u) - (y + v)i$$
$$= \alpha(x + iy) + \alpha(u + iv)$$
$$\alpha((x + iy)(u + iv)) = \alpha(xu - yv + i(xv + yu))$$
$$= xu - yv - i(xv + yu)$$
$$= (x - iy)(u - iv)$$
$$= \alpha(x + iy)\alpha(u + iv)$$

2. Let $K$ be the set of complex numbers of the form $p + q\sqrt{2}$, where $p, q \in \mathbb{Q}$. This is a subfield of $\mathbb{C}$, because

$$(p + q\sqrt{2})^{-1} = \frac{p}{p^2 - 2q^2} - \frac{q}{p^2 - 2q^2}\sqrt{2}$$

if $p$ and $q$ are nonzero. The map $p + q\sqrt{2} \mapsto p - q\sqrt{2}$ is an automorphism of $K$.

3. Let $\alpha = \sqrt{2} \in \mathbb{R}$, and let $\omega$ be a primitive cube root of unity in $\mathbb{C}$. The set of all numbers $p + q\alpha + r\alpha^2$, for $p, q, r \in \mathbb{Q}$, is a subfield of $\mathbb{C}$ (see Exercise 1.5). The map

$$p + q\alpha + r\alpha^2 \mapsto p + q\omega\alpha + r\omega^2\alpha^2$$

is a monomorphism onto its image, but not an automorphism (Exercise 1.6).
1.3 Solving Equations

A physicist friend of mine once told me that while every physicist knew what the big problems of physics were, his mathematical colleagues never seemed to be able to tell him what the big problems of mathematics were. It took me a while to realise that this doesn't mean that they don't know, and even longer to articulate why. The reason, I claim, is that the big problems of physics, at any given moment, are very specific challenges: measure the speed of light, prove that the Higgs boson exists, find a theory to explain high-temperature superconductors. Mathematics has problems like that, too, indeed, Galois tackled one of them — prove that the quintic cannot be solved by radicals. But the big problems of mathematics are more general, and less subject to fashion (or disappearance by virtue of being solved). They are things like “find out how to solve equations like this one”, “find out what shape things like this are”, or even “find out how many of these gadgets can exist”. Mathematicians know this, but it is so deeply ingrained in their way of thinking that they are seldom conscious of it. But such problems have given rise to entire fields of mathematics, here, respectively, algebra, topology, and combinatorics. I mention this because it is the first of the above big problems that runs like an ancient river through the middle of the territory we are going to explore. Find out how to solve equations. Or, as often as not, prove that it cannot be done with specified methods.

What sort of equations? For Galois: polynomials. But let’s work up to those in easy stages.

The usual reason for introducing a new kind of number is that the old ones are inadequate for solving some important problem. Most of the historical problems in this area can be formulated using equations, though it must be said that this is a modern interpretation and the ancient mathematicians did not think in quite those terms.

For example, the step from \( \mathbb{N} \) to \( \mathbb{Z} \) is needed because although some equations, such as

\[ t + 2 = 7 \]

can be solved for \( t \in \mathbb{N} \), others, such as

\[ t + 7 = 2 \]

cannot. However, such equations can be solved in \( \mathbb{Z} \). (The symbol \( x \) is more traditional than \( t \) here, but it is convenient to standardise on \( t \) for the rest of the book, so we may as well start straight away.)

Similarly, the step from \( \mathbb{Z} \) to \( \mathbb{Q} \) (historically, it was initially from \( \mathbb{N} \) to \( \mathbb{Q}^+ \), the positive rationals) makes it possible to solve the equation

\[ 2t = 7 \]

Equations of the form

\[ at + b = 0 \]
where \( a, b \) are specific numbers and \( t \) is an unknown number, or variable, are called \textit{linear equations}. In a subfield of \( \mathbb{C} \), any linear equation with \( a \neq 0 \) can be solved with the unique solution \( t = -b/a \).

The step from \( \mathbb{Q} \) to \( \mathbb{R} \) is related to a different kind of equation:

\[
t^2 = 2
\]

As the ancient Greeks understood (though in their own geometric manner; they did not possess algebraic notation and thought in a very different way from modern mathematicians), the "solution" \( t = \sqrt{2} \) is an \textit{irrational} number — it is not in \( \mathbb{Q} \). (See Exercise 1.2 for a proof, which may be different from the one you have seen before. It is essentially one of the old Greek proofs, translated into algebra. Paul Erdős used to talk of proofs being from "The Book", by which he meant an alleged volume in the possession of the Almighty, in which only the very best mathematical proofs could be found. This Greek proof that the square root of 2 is irrational must surely be in The Book. An entirely different proof of a more general theorem is outlined in Exercise 1.3.)

Similarly, the step from \( \mathbb{R} \) to \( \mathbb{C} \) centres on the equation

\[
t^2 = -1
\]

which has no real solutions since any real number is positive.

Equations of the form

\[
at^2 + bt + c = 0
\]

are called \textit{quadratic equations}. The classic formula for their solutions (there can be 0, 1, or 2 of these) is of course

\[
t = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}
\]

and this gives all the solutions \( t \) provided the formula makes sense. For a start, we need \( a \neq 0 \). (If \( a = 0 \), then the equation is actually linear, so this restriction is not a problem.) Over the real numbers, the formula makes sense if \( b^2 - 4ac \geq 0 \) but not if \( b^2 - 4ac < 0 \); over the complex numbers, it makes sense whatever the sign of \( b^2 - 4ac \) might be. Over the rationals, it makes sense only when \( b^2 - 4ac \) is a perfect square — the square of a rational number.

---

1.4 \textbf{Solution by Radicals}

We begin by reviewing the state of the art regarding solutions of polynomial equations as it was just before the time of Galois. We consider linear, quadratic, cubic, quartic, and quintic equations in turn. In the case of the quintic, we also describe some ideas that were discovered after Galois. Throughout, we make the default assumption of the period: the coefficients of the equation are complex numbers.
1.4.1 Linear Equations

Let $a, b \in \mathbb{C}$ with $a \neq 0$. The general linear equation is

$$at + b = 0$$

and the solution is clearly

$$t = -\frac{b}{a}$$

1.4.2 Quadratic Equations

Let $a, b, c \in \mathbb{C}$ with $a \neq 0$. The general quadratic equation is

$$at^2 + bt + c = 0$$

Dividing by $a$ and renaming the coefficients, we can consider the equivalent equation

$$t^2 + at + b = 0$$

The standard way to solve this equation is to rewrite it in the form

$$\left(t + \frac{a}{2}\right)^2 = \frac{a^2}{4} - b$$

Taking square roots,

$$t + \frac{a}{2} = \pm \sqrt{\frac{a^2}{4} - b}$$

so that

$$t = \frac{1}{2} \left(-\frac{a}{2} \pm \sqrt{\frac{a^2}{4} - b}\right)$$

which is the usual quadratic formula except for a change of notation. The process used here is called completing the square; as remarked in the Historical Introduction, it goes back to the Babylonians 3600 years ago.

1.4.3 Cubic Equations

Let $a, b, c \in \mathbb{C}$ with $a \neq 0$. The general cubic equation can be written in the form

$$t^3 + at^2 + bt + c = 0$$

where again we have divided by the leading coefficient to avoid unnecessary complications in the formulas.
The first step is to change the variable to make \( a = 0 \). This is achieved by setting 
\[ y = t + \frac{a}{3}, \]  
so that 
\[ t = y - \frac{a}{3}. \]  
Such a move is called a Tschirnhaus transformation, after the person who first made explicit and systematic use of it. The equation becomes

\[ y^3 + py + q = 0 \]

where

\[
p = \frac{a^2 - 2a^3 + 3b}{3} \tag{1.2}
\]

\[
q = \frac{2a^3 - 9ab + 27c}{27}
\]

To find the solution(s), we try (rabbit out of hat) the substitution

\[ y = \sqrt[3]{u} + \sqrt[3]{v} \]

Now

\[ y^3 = u + v + 3\sqrt[3]{u}\sqrt[3]{v}(\sqrt[3]{u} + \sqrt[3]{v}) \]

so that Equation (1.2) becomes

\[(u + v + q) + (\sqrt[3]{u} + \sqrt[3]{v})(3\sqrt[3]{u}\sqrt[3]{v} + p) = 0\]

We now choose \( u \) and \( v \) to make both terms vanish:

\[ u + v + q = 0 \quad \tag{1.3} \]

\[ 3\sqrt[3]{u}\sqrt[3]{v} + p = 0 \quad \tag{1.4} \]

which imply

\[ u + v = -q \quad \tag{1.5} \]

\[ uv = -\frac{p^3}{27} \quad \tag{1.6} \]

Multiply Equation (1.5) by \( u \) and subtract Equation (1.6) to get

\[ u(u + v) - uv = -qu + \frac{p^3}{27} \]

which can be rearranged to give

\[ u^2 + qu - \frac{p^3}{27} = 0 \]

which is a quadratic
The solution of quadratics now tells us that
\[ u = -\frac{q}{2} \pm \sqrt{\frac{q^2}{4} + \frac{p^3}{27}} \]

Because \( u + v = q \), we have
\[ v = -\frac{q}{2} \mp \sqrt{\frac{q^2}{4} + \frac{p^3}{27}} \]

Changing the sign of the square root just permutes \( u \) and \( v \), so we can set the sign to +. Thus, we find that
\[
y = \sqrt[3]{-\frac{q}{2} + \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}} + \sqrt[3]{-\frac{q}{2} - \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}} \tag{1.7}
\]

which (by virtue of publication, not discovery) is usually called Cardano's formula. Finally, remember that the solution \( t \) of the original equation is equal to \( y - a/3 \).

### 1.4.4 Peculiarities of Cardano’s Formula

An old Chinese proverb says, “Be careful what you wish for: you might get it”. We have wished for a formula for the solution, and we’ve got one. It has its peculiarities.

First, recall that over \( \mathbb{C} \) every nonzero complex number \( z \) has three cube roots. If one of them is \( \alpha \), then the other two are \( \omega \alpha \) and \( \omega^2 \alpha \), where
\[ \omega = -\frac{1}{2} + i \frac{\sqrt{3}}{2} \]

is a primitive cube root of 1. (A primitive \( n \)th root of unity is an \( n \)th root of 1 that is not an \( m \)th root of 1 for any proper divisor \( m \) of \( n \).) Then
\[ \omega^2 = -\frac{1}{2} - i \frac{\sqrt{3}}{2} \]

The expression for \( y \), therefore, appears to lead to nine solutions of the form
\[
\begin{align*}
\alpha + \beta & \quad \alpha + \omega \beta & \quad \alpha + \omega^2 \beta \\
\omega \alpha + \beta & \quad \omega \alpha + \omega \beta & \quad \omega \alpha + \omega^2 \beta \\
\omega^2 \alpha + \beta & \quad \omega^2 \alpha + \omega \beta & \quad \omega^2 \alpha + \omega^2 \beta
\end{align*}
\]

where \( \alpha, \beta \) are specific choices of the cube roots.

However, not all of these expressions are zeros. Equation (1.4) implies Equation (1.6), but Equation (1.6) implies Equation (1.4) only when we make the correct choices of cube roots. If we choose \( \alpha, \beta \) so that \( 3\alpha \beta + p = 0 \), then the solutions are
\[
\begin{align*}
\alpha + \beta & \quad \omega \alpha + \omega^2 \beta & \quad \omega^2 \alpha + \omega \beta
\end{align*}
\]
Other peculiarities emerge when we try equations whose solutions are already known to us. For example,
\[ y^3 + 3y - 36 = 0 \]
has the solution \( y = 3 \). Here \( p = 3, q = -36 \), and Cardano’s formula gives
\[ y = \sqrt[3]{-18 + \sqrt{325}} + \sqrt[3]{-18 - \sqrt{325}} \]
which seems a far cry from 3. Further algebra converts it to 3 (see Exercise 1.4).

As Cardano observed in his book, it gets worse. The eponymous formula applied to
\[ t^3 - 15t - 4 = 0 \]  
leads to
\[ t = \sqrt{2 + \sqrt{-121}} + \sqrt{2 - \sqrt{-121}} \]
in contrast to the obvious solution \( t = 4 \). Cardano had already encountered such baffling expressions when trying to solve the quadratic \( t(10 - t) = 40 \) with the apparently nonsensical solutions \( 5 + \sqrt{-15} \) and \( 5 - \sqrt{-15} \), but there it was possible to see the puzzling form of the solution as expressing the fact that no solution exists. However, Cardano was bright enough to spot that if you ignore the question of what such expressions mean, and just manipulate them as if they are ordinary numbers, then they do indeed satisfy the equation. “So,” Cardano commented, “progresses arithmetic subtlety, the end of which is as refined as it is useless.”

However, this shed no light on why a cubic could possess a perfectly reasonable solution, but the formula (more properly, the equivalent numerical procedure) could not find it. Around 1560 Raphael Bombelli discovered that \((2 \pm \sqrt{-1})^3 = 2 \pm \sqrt{-121} \), and recovered (see Exercise 1.7) the solution \( t = 4 \) of (1.8) from the formula (1.9), again assuming that such expressions can be manipulated just like ordinary numbers. But Bombelli, too, expressed scepticism that such manoeuvres had any sensible meaning. In 1629 Albert Girard argued that such expressions are valid as formal solutions of the equations, and should be included “for the certitude of the general rules”. Girard was influential in making negative numbers acceptable, but he was way ahead of his time when it came to their square roots.

In fact, Cardano’s formula is pretty much useless whenever the cubic has three real roots. The traditional escape route is to use trigonometric functions (Exercise 1.8). All this rather baffled the Renaissance mathematicians, who did not even have effective algebraic notation and were wary of negative numbers, let alone imaginary ones.

### 1.4.5 Quartic Equations

Start with
\[ \alpha t^4 + \beta t^3 + \gamma t^2 + \delta t + \delta = 0 \]
Make the Tschirnhaus transformation \( y = t + a/4 \) to get

\[
y^4 + py^2 + qy + r = 0 \tag{1.10}
\]

where

\[
p = b - \frac{3a}{8}
\]

\[
q = c - \frac{ab}{2} + \frac{a^2}{4}
\]

\[
r = d - \frac{ac}{4} + \frac{a^2b}{16} - \frac{3a^4}{256}
\]

Rewrite this in the form

\[
\left( y^2 + \frac{p}{2} \right)^2 = -qy - r + \frac{p^2}{4}
\]

Introduce a new term \( u \), and observe that

\[
\left( y^2 + \frac{p}{2} + u \right)^2 = \left( y^2 + \frac{p}{2} \right)^2 + 2 \left( y^2 + \frac{p}{2} \right) u + u^2
\]

\[
= -qy - r + \frac{p^2}{4} + 2uy + pu + u^2
\]

We choose \( u \) to make the right-hand side a perfect square. If it is, it must be the square of \( \sqrt{2uy - \frac{q}{2} \sqrt{2u}} \), and then we require

\[
-r + \frac{p^2}{4} + pu + u^2 = \frac{q^2}{8u}
\]

Equivalently, provided \( u \neq 0 \),

\[
8u^3 + 8pu^2 + (2p - 8r)u - q^2 = 0 \tag{1.11}
\]

which is a cubic in \( u \). Solving by Cardano’s method, we can find \( u \). Now

\[
\left( y^2 + \frac{p}{2} + u \right)^2 = \left( \sqrt{2uy - \frac{q}{2} \sqrt{2u}} \right)^2
\]

so

\[
y^2 + \frac{p}{2} + u = \pm \left( \sqrt{2uy - \frac{q}{2} \sqrt{2u}} \right)
\]

Finally, we can solve the above two quadratics to find \( y \).

If \( u = 0 \) we do not obtain Equation (1.11), but if \( u = 0 \), then \( q = 0 \), so the quartic Equation (1.10) is a quadratic in \( y^2 \), and can be solved using only square roots.
Equation (1.11) is called the resolvent cubic of Equation (1.10). Explicit formulas for the roots can be obtained if required. Because they are complicated, we shall not give them here.

1.4.6 Quintic Equations

So far, we have a series of special tricks, different in each case. We can start to solve the general quintic

\[ t^5 + at^4 + bt^3 + ct^2 + dt + e = 0 \]

in a similar way. A Tschirnhaus transformation \( y = t + a/5 \) reduces it to

\[ y^5 + py^3 + qy^2 + ry + s = 0 \]

However, all variations on the tricks that we used for the quadratic, cubic, and quartic equations grind to a halt.

Lagrange, in 1770–1771, analysed all of the above special tricks, and showed that they can all be explained using general principles about symmetric functions of the roots. When he applied this method to the quintic, however, he found that it reduced the problem to solving a sextic — an equation of degree 6. Instead of helping, the method now made the problem worse. A fascinating description of these ideas, together with a method for solving quintics whenever they are soluble by radicals, can be found in a lecture by George Neville Watson that was rescued from his unpublished papers and written up by Berndt, Spearman, and Williams (2002). The same article contains a wealth of other information about the quintic, including a long list of historical and recent references. Because the formulas are messy and the story is lengthy, the most we can do here is give some flavour of what is involved.

Lagrange observed that all methods for solving polynomial equations by radicals involve constructing rational functions of the roots that take a small number of values when the roots \( \alpha_j \) are permuted. Prominent among these is the expression

\[ \delta = \prod_{j < k} (\alpha_j - \alpha_k) \]

which takes just two values, \( \pm \delta \): plus for even permutations and minus for odd ones. Therefore, \( \Delta = \delta^2 \) (known as the discriminant because it is nonzero precisely when the roots are distinct, so it discriminates among the roots) is a rational function of the coefficients. This gets us started, and it yields a complete solution for the quadratic, but for cubics upward it does not help much unless we can find other expressions in the roots with similar properties under permutation.

Lagrange worked out what these expressions look like for the cubic and the quartic, and noticed a pattern. For example, if a cubic polynomial has roots \( \alpha_1, \alpha_2, \alpha_3 \) and \( \omega \) is a primitive cube root of unity, then the expression

\[ u = (\alpha_1 + \omega \alpha_2 + \omega^2 \alpha_2)^3 \]
takes exactly two distinct values. In fact, even permutations leave it unchanged, while odd permutations transform it to

\[ v = (\alpha_1 + \omega^2 \alpha_2 + \omega \alpha_3)^3 \]

It follows that \( u + v \) and \( uv \) are fixed by all permutations of the roots and must, therefore, be expressible as rational functions of the coefficients. That is, \( u \) and \( v \) are solutions of a quadratic equation, and can thus be expressed using square roots. But now the further use of cube roots expresses \( \alpha_1 + \omega \alpha_2 + \omega^2 \alpha_3 = \sqrt[3]{u} \) and \( \alpha_1 + \omega^2 \alpha_2 + \omega \alpha_3 = \sqrt[3]{v} \) by radicals. Because we also know that \( \alpha_1 + \alpha_2 + \alpha_3 \) is minus the coefficient of \( t^2 \), we have three independent linear equations in the roots, which are easily solved.

Something very similar works for the quartic, with expressions like

\[ (\alpha_1 + i \alpha_2 + i^2 \alpha_3 + i^3 \alpha_4)^4 \]

But when we try the same idea on the quintic, an obstacle appears. Suppose that the roots of the quintic are \( \alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5 \). Let \( \zeta \) be a primitive fifth root of unity. Following Lagrange's lead, it is natural to consider

\[ w = (\alpha_1 + \zeta \alpha_2 + \zeta^2 \alpha_3 + \zeta^3 \alpha_4 + \zeta^4 \alpha_5)^5 \]

There are 120 permutations of 5 roots, and they transform \( w \) into 24 distinct expressions. Therefore, \( w \) is a root of a polynomial of degree 24 — a big step in the wrong direction, because we started with a mere quintic.

The best that can be done is to use an expression derived by Arthur Cayley in 1861, based on an idea of Robert Harley in 1859. This expression is

\[ x = (\alpha_1 \alpha_2 + \alpha_2 \alpha_3 + \alpha_3 \alpha_4 + \alpha_4 \alpha_5 + \alpha_5 \alpha_1 - \alpha_1 \alpha_3 - \alpha_2 \alpha_4 - \alpha_3 \alpha_5 - \alpha_4 \alpha_1 - \alpha_5 \alpha_2)^2 \]

It turns out that \( x \) takes precisely 6 values when the variables are permuted in all 120 possible ways. Therefore, \( x \) is a root of a sextic equation. The equation is very complicated and has no obvious roots; it is, perhaps, better than an equation of degree 24, but it is still no improvement on the original quintic. Except when the sextic happens, by accident, to have a root whose square is rational, in which case the quintic is solvable by radicals. Indeed, this is a necessary and sufficient condition for a quintic to be soluble by radicals, see Berndt, Spearman, and Williams (2002). For instance, as they explain in detail, the equation

\[ t^5 + 15t + 12 = 0 \]

has the solution

\[ t = \sqrt[5]{-75 + 21\sqrt{10}} + \sqrt[5]{-75 - 21\sqrt{10}} + \sqrt[5]{225 + 72\sqrt{10}} + \sqrt[5]{225 - 72\sqrt{10}} \]

with similar expressions for the other four roots.
Lagrange's general method, then, fails for the quintic. This does not prove that the general quintic is not soluble by radicals, because for all Lagrange or anyone else knew, there might be other methods that do not make the problem worse. But it does suggest that there is something very different about the quintic. Suspicion began to grow that no method would solve the quintic by radicals. Mathematicians stopped looking for such a solution, and started looking for an impossibility proof instead.

Exercises

1.1 Use (1.1) to prove that multiplication of complex numbers is commutative and associative. That is, if \( u, v, w \) are complex numbers, then \( uv = vu \) and \( (uv)w = u(vw) \).

1.2 Prove that \( \sqrt{2} \) is irrational, as follows. Assume for a contradiction that there exist integers \( a, b \), with \( b \neq 0 \), such that \( (a/b)^2 = 2 \).

1. Show that we may assume \( a, b > 0 \).

2. Observe that if such an expression exists, then there must be one in which \( b \) is as small as possible.

3. Show that

\[
\left( \frac{2b - a}{a - b} \right)^2 = 2
\]

4. Show that \( 2b - a > 0, a - b > 0 \).

5. Show that \( a - b < b \), a contradiction.

1.3 Prove that if \( q \in \mathbb{Q} \) then \( \sqrt{q} \) is rational if and only if \( q \) is a perfect square; that is, its prime factorization is of the form \( q = p_1^{a_1} \cdots p_n^{a_n} \) where the integers \( a_j \), which may be positive or negative, are all even.

1.4* Prove that

\[
\sqrt[3]{-18} + \sqrt[3]{325} + \sqrt[3]{-18 - \sqrt{325}} = 3
\]

1.5 Let \( \alpha = \sqrt{2} \in \mathbb{R} \), and let \( \omega \) be a primitive cube root of unity in \( \mathbb{C} \). Prove that the set of all numbers \( p + q\alpha + r\alpha^2 \), for \( p, q, r \in \mathbb{Q} \), is a subfield of \( \mathbb{C} \).

1.6 With the notation of Exercise 1.5, show that the map

\[
p + q\alpha + r\alpha^2 \mapsto p + q\omega\alpha + r\omega^2\alpha^2
\]

is a monomorphism onto its image, but not an automorphism.
1.7 Use Bombelli’s observation that \((2 \pm \sqrt{-1})^3 = 2 \pm \sqrt{-121}\) to show that (with one choice of values of the cube roots)

\[
\sqrt[3]{2 + \sqrt{-121}} + \sqrt[3]{2 - \sqrt{-121}} = 4
\]

1.8 Use the identity \(\cos 3\theta = 4\cos^3 \theta - 3\cos \theta\) to solve the cubic equation \(t^3 + pt + q = 0\) when \(27q^2 + 4p^3 < 0\).

1.9 Find radical expressions for all three roots of \(t^3 - 15t - 4 = 0\).

1.10 When \(27q^2 + 4p^3 < 0\) it is possible to try to make sense of Cardano’s formula by generalizing Bombelli’s observation; that is, to seek \(\alpha, \beta\) such that

\[
\left[ \alpha \pm \beta \sqrt{\frac{q^2}{4} + \frac{p^3}{27}} \right]^3 = \frac{q}{2} \pm \sqrt{\frac{q^2}{4} + \frac{p^3}{27}}
\]

Why is this usually pointless?

1.11* Let \(P(n)\) be the number of ways to arrange \(n\) zeros and ones in a row, given that ones occur in groups of three or more. Show that

\[
P(n) = 2P(n - 1) - P(n - 2) + P(n - 4)
\]

and deduce that as \(n \to \infty\) the ratio \(\frac{P(n+1)}{P(n)} \to x\), where \(x > 0\) is real and \(x^4 - 2x^3 + x^2 - 1 = 0\). Factorize this quartic as a product of two quadratics, and hence find \(x\).

1.12* The largest square that fits inside an equilateral triangle can be placed in any of three symmetrically related positions. Eugenio Calabi noticed that there is exactly one other shape of triangle in which there are three equal largest squares (Figure 1.1). Prove that in this triangle the ratio \(x\) of the longest side to either

Figure 1.1: Calabi's triangle.
of the shorter ones is a solution of the cubic equation \(2x^3 - 2x^2 - 3x + 2 = 0\),
and find an approximate value of \(x\) to three decimal places.

1.13 Mark the following true or false.

a. \(-1\) has no square root.
b. \(-i\) has no real square root.
c. \(-1\) has two distinct square roots in \(\mathbb{C}\).
d. Every subring of \(\mathbb{C}\) is a subfield of \(\mathbb{C}\).
e. Every subfield of \(\mathbb{C}\) is a subring of \(\mathbb{C}\).
f. The set of all numbers \(p + q\sqrt{5}\) for \(p, q \in \mathbb{Q}\) is a subring of \(\mathbb{C}\).
g. The set of all numbers \(p + q\sqrt{5}\) for \(p, q \in \mathbb{C}\) is a subring of \(\mathbb{C}\).
h. Cardano's formula always gives a correct answer.
i. Cardano's formula always gives a sensible answer.
j. A quintic equation over \(\mathbb{Q}\) can never be solved by radicals.
Chapter 2

The Fundamental Theorem of Algebra

At the time of Galois, the natural setting for most mathematical investigations was the complex number system. The real numbers were inadequate for many questions, because $-1$ has no real square root. The arithmetic, algebra, and — decisively — analysis of complex numbers were richer, more elegant, and more complete than the corresponding theories for real numbers.

In this chapter we establish one of the key properties of $\mathbb{C}$, known as the Fundamental Theorem of Algebra. This theorem asserts that every polynomial equation with coefficients in $\mathbb{C}$ has a solution in $\mathbb{C}$. This theorem is, of course, false over $\mathbb{R}$; take $t^2 + 1 = 0$. It was fundamental to classical algebra, but the name is somewhat archaic, and modern algebra bypasses $\mathbb{C}$ altogether, preferring greater generality. Because we find it convenient to work in the same setting as Galois, the theorem is fundamental for us.

However, all rigorous proofs of the Fundamental Theorem of Algebra require quite a lot of background. Here, we approach the proof using some simple topological ideas. These ideas are intuitively plausible, but setting them up in full logical rigour involves some subtleties, which we ignore here.

Later, we give an almost purely algebraic proof, using much more machinery (see Chapter 23). Ironically, that proof uses Galois theory to prove the Fundamental Theorem of Algebra, the exact opposite of what Galois did. The logic is not circular, because the proof in Chapter 23 rests on the abstract approach to Galois theory described in the second part of this book, which makes no use of the Fundamental Theorem of Algebra.

2.1 Polynomials

Linear, quadratic, cubic, quartic, and quintic equations are examples of a more general class: polynomial equations. These take the form

$$p(t) = 0$$

where $p(t)$ is a polynomial in $t$.

Mathematics is littered with polynomial equations arising in a huge variety of contexts. As a sample, here are two from the literature. You don't need to think about them: just observe them like a butterfly collector looking at a strange new specimen.
In connection with the so-called look and say sequence, John Horton Conway came up with one of the strangest instances of a polynomial equation that I have ever encountered. The sequence starts

\[ 1 \ 11 \ 21 \ 1211 \ 111221 \ 3112211 \ 13112221 \ldots \]

The rule of formation is most readily seen in verbal form. We start with "1," which can be read as "one one," so the next term is 11. This reads "two ones," leading to 21. Read this as "one two, one one" and you see where 1211 comes from, and so on. If \( L(n) \) is the length of the \( n \)th term in this sequence, approximately how big is \( L(n) \)? Conway (1985) proves that \( L(n) \) satisfies a 72-term linear recurrence relation. Standard techniques from combinatorics then prove that \( L(n) \) is roughly proportional to \( \alpha^n \), where \( \alpha = 1 \cdot 303577 \ldots \) is the smallest real solution of the 71st degree polynomial equation

\[
t^{71} - t^{69} - 2t^{68} - t^{67} + 2t^{66} + 2t^{65} - t^{63} - t^{62} - t^{61} - t^{60} + 2t^{58} + 5t^{57} + 3t^{56} - 2t^{55} - 10t^{54} - 3t^{53} - 2t^{52} + 6t^{51} + 6t^{50} + t^{49} + 9t^{48} - 3t^{47} - 7t^{46} - 8t^{45} + 8t^{44} + 10t^{43} + 6t^{42} + 8t^{41} - 5t^{40} - 12t^{39} + 7t^{38} - 7t^{37} + 7t^{36} + t^{35} - 3t^{34} + 10t^{33} + t^{32} - 6t^{31} - 2t^{30} - 10t^{29} - 3t^{28} + 2t^{27} + 9t^{26} - 3t^{25} + 14t^{24} - 8t^{23} - 7t^{21} + 9t^{20} + 3t^{19} - 4t^{18} - 10t^{17} - 7t^{16} + 12t^{15} + 7t^{14} + 2t^{13} - 12t^{12} - 4t^{11} - 2t^{10} + 5t^9 + t^7 - 7t^6 + 7t^5 - 4t^4 + 12t^3 - 6t^2 + 3t - 6 = 0
\]

Our second example is from frontier research in cosmology. Braden et al. (1990) show that the entropy of a black hole is \( \pi r_h^2 \alpha^2 \), where \( \alpha \) is a solution of the 7th degree equation

\[ t^5(t - q^2)(t - 1) + b^2(t^2 - q^2)^2 = 0 \]

where \( b, q \) are expressions involving temperature and various fundamental physical constants such as the speed of light and Planck's constant.

With the case for the importance of polynomial equations now clear, we start to develop a coherent theory of their solutions. As the above examples illustrate, a polynomial is an algebraic expression involving the powers of a variable or indeterminate \( t \). We are used to thinking of such a polynomial as the function that maps \( t \) to the value of the expression concerned, so that the first polynomial represents the function \( f \) such that \( f(t) = t^2 - 2t + 6 \). This function viewpoint is familiar, and it causes no problems when we are thinking about polynomials with complex numbers as their coefficients. Later (Chapter 16) we will see that when more general fields are permitted, it is not such a good idea to think of a polynomial as a function. So it is worth setting up the concept of a polynomial so that it extends easily to the general context.

We, therefore, define a polynomial over \( \mathbb{C} \) in the indeterminate \( t \) to be an expression

\[ r_0 + r_1 t + \cdots + r_n t^n \]

where \( r_0, \ldots, r_n \in \mathbb{C} \), \( 0 \leq n \in \mathbb{Z} \), and \( t \) is undefined. What, though, is an expression, logically speaking? For set theoretic purity we can replace such an expression...
2.1 Polynomials

by the sequence \((r_0, \ldots, r_n)\) (see Exercise 2.2). In such a formalism, \(t\) is just a placeholder for the sequence \((0, 1, \ldots, 0)\).

The elements \(r_0, \ldots, r_n\) are the coefficients of the polynomial. In the usual way, terms \(0 t^m\) may be omitted or written as \(0\), and \(1 t^m\) can be replaced by \(t^m\).

Two polynomials are defined to be equal if and only if the corresponding coefficients are equal, with the understanding that powers of \(t\) not occurring in the polynomial may be taken to have zero coefficient. To define the sum and the product of two polynomials, write

\[
\sum r_i t^i
\]

instead of

\[
 r_0 + r_1 t + \cdots + r_n t^n
\]

where the summation is considered as being over all integers \(i \geq 0\), and \(r_k\) is defined to be 0 if \(k \geq n\). Then, if

\[
 r = \sum r_i t^i \quad s = \sum s_i t^i
\]

we define

\[
 r + s = \sum (r_i + s_i) t^i \quad (2.1)
\]

and

\[
 rs = \sum q_j t^j \quad \text{where} \quad q_j = \sum_{h+i=j} r_h s_i \quad (2.2)
\]

It is now easy to check directly from these definitions that the set of all polynomials over \(\mathbb{C}\) in the \(t\) obeys all of the usual algebraic laws (Exercise 2.3). We denote this set by \(\mathbb{C}[t]\), and call it the ring of polynomials over \(\mathbb{C}\) in the indeterminate \(t\).

We can also define polynomials in several indeterminates \(t_1, t_2, \ldots, t_n\), obtaining the ring of \(n\)-variable polynomials

\[
\mathbb{C}[t_1, t_2, \ldots, t_n]
\]

in an analogous way.

An element of \(\mathbb{C}[t]\) will usually be denoted by a single letter, such as \(f\), whenever it is clear which indeterminate is involved. If there is ambiguity, we write \(f(t)\) to emphasize the role played by \(t\).

Next, we introduce a simple but very useful concept that quantifies how complicated a polynomial is.

**Definition 2.1** If \(f\) is a polynomial over \(\mathbb{C}\) and \(f \neq 0\), then the degree of \(f\) is the highest power of \(t\) occurring in \(f\) with nonzero coefficient.
For example, \( t^2 + 1 \) has degree 2, and \( 723t^{1101} - 911t^{55} + 43 \) has degree 1101. More generally, if \( f = \sum r_i t^i \) and \( r_n \neq 0 \) and \( r_m = 0 \) for \( m > n \), then \( f \) has degree \( n \).

We write \( \partial f \) for the degree of \( f \). To deal with the case \( f = 0 \) we adopt the convention that \( \partial 0 = -\infty \) (which symbol is endowed with the following properties: \(-\infty < n \) for any integer \( n \), \(-\infty + n = -\infty \), \(-\infty \times n = -\infty \), \((-\infty)^2 = -\infty \)).

The following result is immediate from this definition.

**PROPOSITION 2.2**

If \( f, g \) are polynomials over \( \mathbb{C} \), then

\[
\partial(f + g) \leq \max(\partial f, \partial g) \quad \partial(fg) = \partial f + \partial g
\]

The inequality in the first line is due to the possibility of the highest terms cancelling (see Exercise 2.4).

The \( f(t) \) notation makes \( f \) appear to be a function, with \( t \) as its independent variable, and in fact we can identify each polynomial \( f \) over \( \mathbb{C} \) with the corresponding function. Specifically, each polynomial \( f \in \mathbb{C}[t] \) can be considered as a function from \( \mathbb{C} \) to \( \mathbb{C} \), defined as follows: if \( f = \sum r_i t^i \) and \( \alpha \in \mathbb{C} \), then \( \alpha \) is mapped to \( \sum r_i \alpha^i \). The next proposition proves that when the coefficients lie in \( \mathbb{C} \), it causes no confusion if we use the same symbols \( f \) to denote a polynomial and the function associated with it.

**PROPOSITION 2.3**

Two polynomials \( f, g \) over \( \mathbb{C} \) define the same function if and only if they have the same coefficients.

**PROOF** Equivalently, by taking the difference of the two polynomials, we must prove that if \( f(t) \) is a polynomial over \( \mathbb{C} \) and \( f(t) = 0 \) for all \( t \), then the coefficients of \( f \) are all 0. Write

\[
f(t) = a_{n-1} t^{n-1} + \cdots + a_0
\]

We now use complex differentiation. For a purely algebraic proof see Exercise 2.5. Because \( f(t) = 0 \) for all \( t \in \mathbb{C} \), we may differentiate \( n \) times to deduce that \( f^{(n)}(t) = 0 \) for all \( t \in \mathbb{C} \). In particular, \( f^{(n)}(0) = 0 \) for all \( n \). But a simple induction shows that \( f^{(n)}(0) = n! a_n \), so \( a_n = 0 \) for all \( n \).

Proposition 2.2 implies that we can safely consider a polynomial over a subfield of \( \mathbb{C} \) as either a formal algebraic expression or a function. It is easy to see that sums and products of polynomials agree with the corresponding sums and products of functions. Moreover, the same notational flexibility allows us to change the variable in a polynomial. For example, if \( t, u \) are two indeterminates and \( f(t) = \sum r_i t^i \), then we may define \( f(u) = \sum r_i u^i \). It is also clear what is meant by such expressions as \( f(t - 3) \) or \( f(t^2 + 1) \).
2.2 Fundamental Theorem of Algebra

In Section 1.3 we saw that the development of the complex numbers can be viewed as the culmination of a series of successive extensions of the natural number system. At each step, equations that cannot be solved within the existing number system become soluble in the new, extended system. For example, \( \mathbb{C} \) arises from \( \mathbb{R} \) by insisting that \( i^2 = -1 \) should have a solution.

The question then arises: why stop at \( \mathbb{C} \)? Why not find an equation that has no solutions over \( \mathbb{C} \), and enlarge the number system still further to provide a solution?

The answer is that no such equation exists, at least if we limit ourselves to polynomials. Every polynomial equation over \( \mathbb{C} \) has a solution in \( \mathbb{C} \). This proposition was a matter of heated debate around 1700. In a paper of 1702, Leibniz disputes that it can be true, citing the example

\[
x^4 + a^4 = \left( x + a \sqrt[4]{-1} \right) \left( x - a \sqrt[4]{-1} \right) \left( x + a \sqrt[4]{-1} \right) \left( x - a \sqrt[4]{-1} \right)
\]

However, in 1676 Isaac Newton had already observed the factorization into real quadratics:

\[
x^4 + a^4 = (x^2 + a^2)^2 - 2a^2x^2 = (x^2 + a^2 + \sqrt{2}ax)(x^2 + a^2 - \sqrt{2}ax)
\]

and Nicholas Bernoulli published the same formula in 1719. The resolution of the dispute rests on observing that \( \sqrt{i} = \frac{1+i}{\sqrt{2}} \). In 1742 Euler asserted, without proof, that every real polynomial can be decomposed into linear or quadratic factors with real coefficients; Bernoulli now erred the other way, citing

\[
x^4 - 4x^3 + 2x^2 + 4x + 4
\]

with zeros \( 1 + \sqrt{2 + \sqrt{-3}}, 1 - \sqrt{2 + \sqrt{-3}}, 1 + \sqrt{2 - \sqrt{-3}}, \) and \( 1 - \sqrt{2 - \sqrt{-3}} \).

Euler responded, in a letter to his friend Christian Goldbach, that the four factors occur as two complex conjugate pairs, and that the product of such a pair of factors is a real quadratic. He showed this to be the case for Bernoulli’s proposed counterexample. Goldbach suggested that \( x^4 + 72x - 20 \) did not agree with Euler’s assertion, and Euler pointed out a computational error, adding that he had proved the theorem for polynomials of degree \( \leq 6 \). Euler and Jean Le Rond d’Almbert gave incomplete proofs for any degree; Lagrange claimed to have filled in the gaps in Euler’s proof in 1772, but made the mistake of assuming that the roots existed, and that using the laws of algebra to deduce that they must be complex numbers, without proving that the roots — whatever they were — must obey the laws of algebra. The first genuine proof was given by Gauss in his doctoral thesis of 1799. Later, Gauss gave three other proofs, all based on different ideas.

We now state this property of the complex numbers formally, and explore some of its easier consequences; it is the aforementioned Fundamental Theorem of Algebra. As we have observed, this is a good name if we are thinking of classical algebra, but...
not such a good name in the context of modern abstract algebra, which constructs suitable fields as it goes along and avoids explicit use of complex numbers.

**THEOREM 2.4 (Fundamental Theorem of Algebra)**

Let $p(t)$ be a polynomial over $\mathbb{C}$, with $\partial p \geq 1$. Then there exists at least one $z \in \mathbb{C}$ such that $p(z) = 0$.

Such a number $z$ is called a *root* of the equation $p(t) = 0$, or a *zero* of the polynomial $p$. For example, $i$ is a root of the equation $t^2 + 1 = 0$ and a zero of $t^2 + 1$. Polynomial equations may have more than one root; indeed, $t^2 + 1 = 0$ has at least one other root, $-i$.

In this section we prove the Fundamental Theorem of Algebra using some relatively simple ideas from real analysis and topology. This section can be skipped if you wish; the methods are not used again. A proof that is almost purely algebraic will be given in Chapter 23, Corollary 13, but we need to develop Galois theory to make the proof rigorous. Many other proofs exist; one of the most common uses complex analysis (see Stewart and Tall (1983) Theorem 10.7).

The ideas behind the proof we give here (but not their precise expression) go back to Gauss, who disguised the underlying geometry by converting it into complicated trigonometric formulas. For technical reasons, we use different tactics from those employed in the usual version of this proof. The main idea is to consider the winding number of a curve, and we start by describing that.

Let $S$ denote the unit circle, parametrized by arc length $\theta$. We can think of $\theta$ in two equivalent ways. Either $\theta \in \mathbb{R}$ and we identify $\theta + 2k\pi$ with $\theta$ for any integer $k$, which effectively reduces $\theta$ to the range $[0, 2\pi)$, or we think of $\theta$ as an element of the quotient group $\mathbb{R}/2\pi\mathbb{Z}$.

A *loop* in $\mathbb{R}^2$ is a continuous map $\gamma : S \to \mathbb{R}^2$, and its image $\gamma(S)$ is a closed curve in the plane $\mathbb{R}^2$.

Suppose that $\gamma(S)$ does not contain the origin $(0, 0) \in \mathbb{R}^2$; that is, $\gamma(\theta) \neq (0, 0)$ for $\theta \in S$. Then any point $(x, y) \in \gamma(S)$ lies on a unique ray through the origin; that is, a half-line extending from the origin to infinity. The *argument* $\phi$ of $(x, y)$ is the angle between the positive $x$-axis and this ray, measured counterclockwise. The argument can be considered as an element of $\mathbb{R}$, and it is unique up to the addition of any integer multiple of $2\pi$. See Figure 2.1.

Using $\theta$ to parametrize $S$, let $\gamma(\theta) = (x_\theta, y_\theta)$. Choose a value $\phi_0$ of the argument of $(x_0, y_0)$. It is intuitively plausible that there exists a unique choice of argument $\phi_{\theta}$ for the point $(x_\theta, y_\theta)$ such that

1. $\phi_{\theta}$ is equal to $\phi_0$ when $\theta = 0$.
2. $\phi_{\theta}$ varies continuously with $\theta$.

It is not hard to prove this using real analysis and some elementary topology. Intuitively, the idea is to walk along the curve $\gamma(S)$ using very small steps, and to choose the unique value of the argument that causes it to change by a very small
2.2 Fundamental Theorem of Algebra

Figure 2.1: Definition of the argument.

Figure 2.2: Winding numbers.

amount at each step. At any rate, we assume that such a choice is possible. We call it a continuous choice of argument for $\gamma$.

**Definition 2.5** Let $\gamma$ be a loop in $\mathbb{R}^2$ not passing through the origin. Let $\phi_0$ be a continuous choice of argument for $\gamma$. Then the winding number of $\gamma$ round the origin is

$$w(\gamma) = \frac{\phi_{2\pi} - \phi_0}{2\pi}$$

This number does not depend on the initial choice $\phi_0$, because starting with $\phi_0 + 2k\pi$ forces us to replace $\phi_0$ by $\phi_0 + 2k\pi$, and the extra $2k\pi$'s cancel. Figure 2.2 illustrates the topology of the winding number.

**Examples 2.6**

1. Suppose that $\gamma$ is constant, say $\gamma(\theta) = (x_0, y_0) \neq (0, 0)$ for all $\theta$. Then the choice $\phi_0$ works for all $\theta$, not just $\theta = 0$; in particular, being constant, it varies continuously with $\theta$. In this case, the winding number is

$$w(\gamma) = \frac{\phi_0 - \phi_0}{2\pi} = 0$$
2. Suppose that \( \gamma(\theta) = e^{n\theta} \) where \( n \in \mathbb{Z} \). Now we can choose \( \phi_\theta = n\theta \). Therefore,

\[
\frac{w(\gamma)}{2\pi} = \frac{2n\pi - 0}{2\pi} = n
\]

The winding number has an important property: it remains constant if \( \gamma \) is continuously deformed, always avoiding passing through the origin. By this we mean the following. Consider a continuous map

\[
\gamma : \mathbb{S} \times [0, 1] \to \mathbb{R}^2 \setminus \{(0, 0)\}
\]

Then \( \gamma \) defines a continuously varying family of loops \( \gamma_\varepsilon \), where \( \gamma_\varepsilon(\theta) = \gamma(\theta, \varepsilon) \). We do not prove this property here, but we note one consequence:

**THEOREM 2.7**

With the above notation, \( w(\gamma_\varepsilon) = w(\gamma_0) \) for all \( \varepsilon \in [0, 1] \). In particular,

\[
w(\gamma_1) = w(\gamma_0)
\]  \hspace{1cm} (2.3)

**PROOF** We sketch the proof. Some topology is needed to justify the assertions made.

The winding numbers are well defined as no \( \gamma_\varepsilon \) meets the origin. The value of \( w(\gamma_\varepsilon) \) varies continuously with \( \varepsilon \). Because it is an integer, it must, therefore, be constant. So \( w(\gamma_\varepsilon) = w(\gamma_0) \) for all \( \varepsilon \in [0, 1] \). Setting \( \varepsilon = 1 \), we have proved Equation (2.3).

If some \( \gamma_\varepsilon \) passes through the origin, then the winding number may change. Figure 2.3 shows how this can happen.

We can now give a topological proof of the Fundamental Theorem of Algebra:

![Diagram](image)

**Figure 2.3:** How the winding number can change when a deformation of the loop passes through the origin.
2.2 Fundamental Theorem of Algebra

PROOF OF THEOREM 2.4 Let \( p(t) \) be a nonconstant polynomial in \( \mathbb{C}[t] \). Without loss of generality we may assume that the highest coefficient of \( p(t) \) is 1. We assume that \( p(t) \) has no zeros in \( \mathbb{C} \) and obtain a contradiction. Let the degree \( \partial p = n \geq 1 \).

For each \( \varepsilon \in [0, 1) \) define a loop \( \gamma_\varepsilon \) by

\[
\gamma_\varepsilon(\theta) = \frac{p(r(\varepsilon)e^{i\theta})}{r(\varepsilon)^n + 1}
\]

where

\[
r(\varepsilon) = \frac{\varepsilon}{1 - \varepsilon}
\]

When \( \varepsilon = 1 \), define

\[
\gamma_1(\theta) = e^{n\theta}
\]

Now \( \gamma_\varepsilon \) is defined for all \( \varepsilon \in [0, 1) \).

We claim that \( \gamma : \mathbb{S} \times [0, 1] \rightarrow \mathbb{R}^2 \) is continuous, where \( \gamma(\theta, \varepsilon) = \gamma_\varepsilon(\theta) \). This is obvious except at \( \varepsilon = 1 \). As \( \varepsilon \to 1 \), the function \( r(\varepsilon) \) tends to \( +\infty \), so

\[
\lim_{\varepsilon \to 1} \gamma_\varepsilon(\theta) = \lim_{r(\varepsilon) \to +\infty} \frac{p(r(\varepsilon)e^{i\theta})}{r(\varepsilon)^n + 1}
\]

Suppose that

\[
p(t) = t^n + a_{n-1}t^{n-1} + \cdots + a_0
\]

Then

\[
\frac{p(r(\varepsilon)e^{i\theta})}{r(\varepsilon)^n + 1} = \frac{r(\varepsilon)^n}{r(\varepsilon)^n + 1} e^{n\theta} + \frac{a_{n-1}r(\varepsilon)^{n-1}e^{(n-1)i\theta} + \cdots + a_0}{r(\varepsilon)^n + 1}
\]

The second term on the right-hand side tends to 0 as \( r(\varepsilon) \) tends to \( +\infty \), and the first term tends to \( e^{n\theta} \). Therefore, for each \( \theta \),

\[
\lim_{\varepsilon \to 1} \gamma_\varepsilon(\theta) = \gamma_1(\theta)
\]

Because we can take \( \theta \) to lie in the closed interval \([0, 2\pi] \), the convergence is uniform in \( \theta \). Therefore, \( \gamma \) is continuous.

The assumption that \( p(z) \) is nonzero for all \( z \in \mathbb{C} \) implies that the curve defined by \( \gamma_\varepsilon \) does not meet the origin for any \( \varepsilon \in [0, 1] \). Indeed, \( \gamma_\varepsilon(\theta) = 0 \) if and only if \( p(r(\varepsilon)e^{i\theta}) = 0 \). By Theorem 2.7, \( w(\gamma_0) = w(\gamma_1) \). However, Examples 2.6 show that \( w(\gamma_0) = 0 \), whereas \( w(\gamma_1) = n \geq 1 \). This is a contradiction. Therefore, the assumption that \( p(t) \) has no zeros in \( \mathbb{C} \) is false, which is what we wish to prove. \( \Box \)
2.3 Implications

The Fundamental Theorem of Algebra has some useful implications. Before proving the most basic of these, we first prove the Remainder Theorem.

**THEOREM 2.8 (Remainder Theorem)**

Let \( p(t) \in \mathbb{C}[t] \) with \( \deg p \geq 1 \), and let \( \alpha \in \mathbb{C} \).

1. There exist \( q(t) \in \mathbb{C}[t] \) and \( r \in \mathbb{C} \) such that \( p(t) = (t - \alpha)q(t) + r \).

2. The constant \( r \) satisfies \( r = p(\alpha) \).

**PROOF** Let \( y = t - \alpha \) so that \( t = y + \alpha \). Write \( p(t) = p_n t^n + \cdots + p_0 \) where \( p_n \neq 0 \) and \( n \geq 1 \). Then

\[
p(t) = p_n (y + \alpha)^n + \cdots + p_0
\]

Expand the powers of \( y + \alpha \) by the binomial theorem, and collect terms to get

\[
p(t) = a_n y^n + \cdots + a_1 y + a_0 \quad a_j \in \mathbb{C}
\]

\[
= y(a_n y^{n-1} + \cdots + a_1) + a_0
\]

\[
= (t - \alpha)q(t) + r
\]

where

\[
q(t) = a_n (t - \alpha)^n + \cdots + a_1 (t - \alpha) + a_0
\]

\[
r = a_0
\]

Now substitute \( t = \alpha \) in the identity \( p(t) = (t - \alpha)q(t) + r \) to get

\[
p(\alpha) = (\alpha - \alpha)q(\alpha) + r = 0.q(\alpha) + r = r
\]

\[\square\]

**COROLLARY 2.9**

The complex number \( \alpha \) is a zero of \( p(t) \) if and only if \( t - \alpha \) divides \( p(t) \) in \( \mathbb{C}[t] \).

**PROPOSITION 2.10**

Let \( p(t) \in \mathbb{C}[t] \) with \( \deg p = n \geq 1 \). Then there exist \( \alpha_1, \ldots, \alpha_n \in \mathbb{C} \), and \( 0 \neq k \in \mathbb{C} \), such that

\[
p(t) = k(t - \alpha_1) \cdots (t - \alpha_n)
\]

(2.4)
PROOF Use induction on \( n \). The case \( n = 1 \) is obvious. If \( n > 1 \) we know, by the Fundamental Theorem of Algebra, that \( p(t) \) has at least one zero in \( \mathbb{C} \); call this zero \( \alpha_n \). By the Remainder Theorem, there exists \( q(t) \in \mathbb{C}[t] \) such that

\[
p(t) = (t - \alpha_n)q(t) \tag{2.5}
\]

(note that the remainder \( r = p(\alpha_n) = 0 \)). Then \( \delta q = n - 1 \), so by induction

\[
q(t) = k(t - \alpha_1) \cdots (t - \alpha_{n-1}) \tag{2.6}
\]

For suitable complex numbers \( k, \alpha_1, \ldots, \alpha_{n-1} \). Substitute Equation (2.6) in Equation (2.5) and the induction step is complete. 

It follows immediately that the \( \alpha_j \) are the only complex zeros of \( p(t) \).

The zeros \( \alpha_j \) need not be distinct. Collecting together those that are equal, we can rewrite Equation (2.4) in the form

\[
p(t) = k(t - \beta_1)^{m_1} \cdots (t - \beta_t)^{m_t}
\]

where the \( \beta_j \) are distinct, the \( m_j \) are integers \( \geq 1 \), and \( m_1 + \cdots + m_t = n \). We call \( m_j \) the multiplicity of the zero \( \beta_j \) of \( p(t) \).

In particular, we have proved that every complex polynomial of degree \( n \) has precisely \( n \) complex zeros, counted according to multiplicity.

---

**Exercises**

2.1 Let \( p(t) \in \mathbb{Q}[t] \). Show that \( p(t) \) has a unique expression in the form

\[
p(t) = (t - \alpha_1) \cdots (t - \alpha_r)q(t)
\]

(except for reordering the \( \alpha_j \)) where \( \alpha_j \in \mathbb{Q} \) for \( 1 \leq j \leq r \) and \( q(t) \) has no zeros in \( \mathbb{Q}[t] \). Prove that here the \( \alpha_j \) are precisely the zeros of \( p(t) \) in \( \mathbb{Q} \).

2.2 A set theorist would define \( \mathbb{C}[t] \) as follows. Consider the set \( S \) of all infinite sequences

\[
(a_n)_{n \in \mathbb{N}} = (a_0, a_1, \ldots, a_n, \ldots)
\]

where \( a_n \in \mathbb{C} \) for all \( n \in \mathbb{N} \), and such that \( a_n = 0 \) for all but a finite set of \( n \). Define operations of addition and multiplication on \( S \) by the rules

\[
(a_n) + (b_n) = (t_n) \quad \text{where} \quad t_n = a_n + b_n
\]

\[
(a_n) \cdot (b_n) = (u_n) \quad \text{where} \quad u_n = a_n b_0 + a_{n-1} b_1 + \cdots + a_0 b_n
\]
Prove that \( \mathbb{C}[t] \), so defined, satisfies all of the usual laws of algebra for addition, subtraction, and multiplication. Define the map

\[
\theta : \mathbb{C} \rightarrow S
\]

\[
\theta(k) = (k, 0, 0, 0, \ldots)
\]

and prove that \( \theta(\mathbb{C}) \subseteq S \) is isomorphic to \( \mathbb{C} \).

Finally, prove that if we identify \( a \in \mathbb{C} \) with \( \theta(a) \in S \) and the indeterminate \( t \) with \( (0, 1, 0, 0, 0, \ldots) \in S \), then \( (a_n) = a_0 + \cdots + a_N t^N \), where \( N \) is chosen so that \( a_n = 0 \) for \( n > N \). Thus we can define polynomials as sequences of complex numbers corresponding to the coefficients.

2.3 Using Equations (2.1, 2.2), prove that polynomials over \( \mathbb{C} \) obey the following algebraic laws:

\[
f + g = g + f, \quad f + (g + h) = (f + g) + h, \quad fg = gf, \quad f(gh) = (fg)h,
\]

and

\[
f(g + h) = fg + fh.
\]

2.4 Show that \( \partial(f + g) \) can be less than \( \max(\partial f, \partial g) \) and, indeed, that \( \partial(f + g) \) can be less than \( \min(\partial f, \partial g) \).

2.5* If \( z_1, z_2, \ldots, z_n \) are distinct complex numbers, show that the determinant

\[
D = \begin{vmatrix}
1 & 1 & \cdots & 1 \\
z_1 & z_2 & \cdots & z_n \\
z_1^2 & z_2^2 & \cdots & z_n^2 \\
\vdots & \vdots & \ddots & \vdots \\
z_1^{n-1} & z_2^{n-1} & \cdots & z_n^{n-1}
\end{vmatrix}
\]

is nonzero.

*(Hint: Consider the \( z_j \) as independent indeterminates over \( \mathbb{C} \). Then \( D \) is a polynomial in the \( z_j \), of total degree \( 0 + 1 + 2 + \cdots + (n - 1) = \frac{1}{2} n(n - 1) \). Moreover, \( D \) vanishes whenever \( z_j = z_k \), for \( k \neq j \), as it then has two identical rows. Therefore \( D \) is divisible by \( z_j - z_k \) for all \( j \neq k \), hence it is divisible by \( \prod_{j<k}(z_j - z_k) \). Now compare degrees.)*

For obscure reasons, the determinant \( D \) is called a Vandermonde determinant (no such expression occurs in Alexandre-Theophile Vandermonde's published writings).

2.6 Use the Vandermonde determinant to prove that if a polynomial \( f(t) \) vanishes for all \( t \in \mathbb{C} \), then all coefficients of \( f \) are zero. *(Hint. Substitute \( t = 1, 2, 3, \ldots \) and solve the resulting system of linear equations for the coefficients.)*
2.7 What is wrong with the following proof of Proposition 2.3?
Suppose \( f(t) = 0 \) for all \( t \in \mathbb{C} \), where \( f(t) = a_n t^n + \cdots + a_0 \). Set \( t = 0 \) to deduce that \( a_0 = 0 \). Then \( f(t) = t(a_n t^{n-1} + \cdots + a_1) = 0 \) for all \( t \in \mathbb{C} \), so \( a_n t^{n-1} + \cdots + a_1 = 0 \) for all \( t \in \mathbb{C} \). By induction on the degree, \( a_n = \cdots = a_1 = 0 \).

2.8 Show that the proof in Exercise 2.7 can be repaired by appealing to continuity of polynomial functions over \( \mathbb{C} \).

2.9 A curve \( \gamma \) in \( \mathbb{C} \) is defined by
\[
\gamma(\theta) = \left( \cos 3\theta, \sin 3\theta + \frac{1}{10} \cos \left( \theta + \frac{\pi}{4} \right) \right)
\]
Find the winding number of \( \gamma \).

2.10 Prove, without using the winding number, that every cubic polynomial over \( \mathbb{R} \) can be expressed as a product of linear factors over \( \mathbb{C} \).

2.11* Do the same for cubic polynomials over \( \mathbb{C} \).

2.12 Let \( \gamma \) be a loop and let \( \hat{\gamma} \) be defined by \( \hat{\gamma}(\theta) = \gamma(2\pi - \theta) \). Prove that \( \hat{\gamma} \) is a loop, and \( w(\hat{\gamma}) = -w(\gamma) \).

2.13 Let \( \gamma_1, \gamma_2 \) be loops, and define \( \gamma_1 + \gamma_2 \) by
\[
(\gamma_1 + \gamma_2)(\theta) = \begin{cases} 
\gamma_1(2\theta) & \text{if } \theta \leq \pi \\
\gamma_2(2\theta - 2\pi) & \text{if } \theta > \pi
\end{cases}
\]
Show that \( \gamma_1 + \gamma_2 \) is a loop, and \( w(\gamma_1 + \gamma_2) = w(\gamma_1) + w(\gamma_2) \).

2.14 Mark the following true or false. Here \( f, g \) are polynomials over \( \mathbb{C} \).

a. \( \partial(f - g) \geq \min(\partial f, \partial g) \).
b. \( \partial(f - g) \leq \min(\partial f, \partial g) \).
c. \( \partial(f - g) \leq \max(\partial f, \partial g) \).
d. \( \partial(f - g) \geq \max(\partial f, \partial g) \).
e. Every polynomial over \( \mathbb{C} \) has at least one zero in \( \mathbb{C} \).
f. Every polynomial over \( \mathbb{C} \) of degree \( \geq 1 \) has at least one zero in \( \mathbb{R} \).
g. The winding number of any loop not passing through the origin is a positive integer.
Chapter 3

Factorization of Polynomials

Not only is there an algebra of polynomials, there is an arithmetic. That is, there are notions analogous to the integer based concepts of divisibility, primes, prime factorization, and highest common factors. These notions are essential for any serious understanding of polynomial equations, and we develop them in this chapter.

It was noticed early on that if \( f \) is a product \( gh \) of polynomials of smaller degree, then the solutions of \( f(t) = 0 \) are precisely those of \( g(t) = 0 \) together with those of \( h(t) = 0 \). For example, to solve the equation

\[
t^3 - 6t^2 + 11t - 6 = 0
\]

we can spot the factorization \((t - 1)(t - 2)(t - 3)\) and deduce that the roots are \( t = 1, 2, 3 \). From this simple idea emerged the arithmetic of polynomials — a systematic study of divisibility properties of polynomials with particular reference to analogies with the integers. In particular, there is an analogue for polynomials of the Euclidean Algorithm for finding the highest common factor of two integers.

In this chapter we define the relevant notions of divisibility and show that there are certain polynomials, the irreducible ones, that play a similar role to prime numbers in the ring of integers. Every polynomial over a given subfield of \( \mathbb{C} \) can be expressed as a product of irreducible polynomials over the same subfield in an essentially unique way. We relate zeros of polynomials to the factorization theory.

Throughout this chapter all polynomials are assumed to lie in \( K[t] \), where \( K \) is a subfield of the complex numbers, or in \( K \), where \( K \) is a subring of the complex numbers. Some theorems are valid over \( R \), while others are valid only over \( K \); we will need both types.

3.1 The Euclidean Algorithm

In number theory, one of the key concepts is divisibility: an integer \( a \) is divisible by an integer \( b \) if there exists an integer \( c \) such that \( a = bc \). For instance, 60 is divisible by 3 because \( 60 = 3 \times 20 \), but 60 is not divisible by 7. Divisibility properties of integers lead to such ideas as primes and factorization. We wish to develop similar ideas for polynomials.

Many important results in the factorization theory of polynomials derive from the observation that one polynomial may always be divided by another provided that a
remainder term is allowed. This is a generalization of the Remainder Theorem, in which \( f \) is assumed to be linear.

**PROPOSITION 3.1 (Division Algorithm)**

Let \( f \) and \( g \) be polynomials over \( K \), and suppose that \( f \) is nonzero. Then there exist unique polynomials \( q \) and \( r \) over \( K \), such that \( g = fq + r \) and \( r \) has a strictly smaller degree than \( f \).

**PROOF** We use induction on the degree of \( g \). If \( \partial g = -\infty \) then \( g = 0 \) and we may take \( q = r = 0 \). If \( \partial g = 0 \) then \( g = k \) is an element of \( K \). If also \( \partial f = 0 \) then \( f \) is an element of \( K \), and we may take \( q = k/f \) and \( r = 0 \). Otherwise, \( \partial f > 0 \) and we may take \( q = 0 \) and \( r = g \). This starts the induction.

Now assume that the result holds for all polynomials of degree \(<n\), and let \( \partial g = n > 0 \). If \( \partial f > \partial g \), then we may as before take \( q = 0 \), \( r = g \). Otherwise,

\[
    f = a_n t^n + \ldots + a_0 \quad g = b_n t^n + \ldots + b_0
\]

where \( a_m \neq 0 \neq b_n \) and \( m < n \). Let

\[
    g_1 = b_n a_m^{-1} t^{n-m} f - g
\]

Because the terms of highest degree cancel (which is the object of the exercise) we have \( \partial g_1 < \partial g \). By induction there are polynomials \( q_1 \) and \( r_1 \) over \( K \) such that \( g_1 = f q_1 + r_1 \) and \( \partial r_1 < \partial f \). Let

\[
    q = b_n a_m^{-1} t^{n-m} - q_1 \quad r = -r_1
\]

Then

\[
    g = f q + r = b_n a_m^{-1} t^{n-m} f - q_1 f - r_1 = g + g_1 - g_1 = g
\]

so \( g = f q + r \); clearly, \( \partial r < \partial f \) as required.

Finally, we prove uniqueness. Suppose that

\[
    g = f q_1 + r_1 = f q_2 + r_2 \quad \text{where } \partial r_1, \partial r_2 < \partial f
\]

Then \( f(q_1 - q_2) = r_2 - r_1 \). By Proposition 2.2, the polynomial on the left has higher degree than that on the right, unless both are zero. Since \( f \neq 0 \) we must have \( q_1 = q_2 \) and \( r_1 = r_2 \). Thus \( q \) and \( r \) are unique.

With the above notation, \( q \) is called the quotient and \( r \) is called the remainder on dividing \( g \) by \( f \). The inductive process we employed to find \( q \) and \( r \) is called the Division Algorithm.
3.1 The Euclidean Algorithm

Example 3.2
Divide \( g(t) = t^4 - 7t^3 + 5t^2 + 4 \) by \( f = t^2 + 3 \) and find the quotient and remainder.

Observe that

\[
    t^2(t^2 + 3) = t^4 + 3t^2
\]

has the same leading coefficient as \( g \). Then

\[
    g - t^2(t^2 + 3) = -7t^3 + 2t^2 + 4
\]

which has the same leading coefficient as

\[
    -7t(t^2 + 3) = -7t^3 - 21t
\]

Therefore,

\[
    g - t^2(t^2 + 3) + 7t(t^2 + 3) = 2t^2 + 21t + 4
\]

which has the same leading coefficient as

\[
    2(t^2 + 3) = 2t^2 + 6
\]

Therefore,

\[
    g - t^2(t^2 + 3) + 7t(t^2 + 3) - 2(t^2 + 3) = 21t - 2
\]

So

\[
    g = (t^2 + 3)(t^2 - 7t + 2) + (21t - 2)
\]

and the quotient \( q(t) = t^2 - 7t + 2 \), while the remainder \( r(t) = 21t - 2 \).

The next step is to introduce notions of divisibility for polynomials, and in particular the idea of highest common factor, which is crucial to the arithmetic of polynomials.

**Definition 3.3** Let \( f \) and \( g \) be polynomials over \( K \). We say that \( f \) divides \( g \) (or \( f \) is a factor of \( g \), or \( g \) is a multiple of \( f \)) if there exists some polynomial \( h \) over \( K \) such that \( g = fh \). The notation \( f \mid g \) will mean that \( f \) divides \( g \), while \( f \nmid g \) will mean that \( f \) does not divide \( g \).

**Definition 3.4** A polynomial \( d \) over \( K \) is a highest common factor (hcf) of polynomials \( f \) and \( g \) over \( K \) if \( d \mid f \) and \( d \mid g \) and further, whenever \( e \mid f \) and \( e \mid g \), we have \( e \mid d \).

Note that we have said a highest common factor rather than the highest common factor. This is because hcf's need not be unique. The next lemma shows that they are unique apart from constant factors.
**Lemma 3.5**

If \(d\) is an hcf of the polynomials \(f\) and \(g\) over \(K\), and if \(0 \neq k \in K\), then \(kd\) is also an hcf for \(f\) and \(g\).

If \(d\) and \(e\) are two hcf's for \(f\) and \(g\), then there exists a nonzero element \(k \in K\) such that \(e = kd\).

**Proof** Clearly, \(kd \mid f\) and \(kd \mid g\). If \(e \mid f\) and \(e \mid g\) then \(e \mid d\) so that \(e \mid kd\). Hence \(kd\) is an hcf. If \(d\) and \(e\) are hcf's then by definition \(e \mid d\) and \(d \mid e\). Thus \(e = kd\) for some polynomial \(K\). Because \(e \mid d\) the degree of \(e\) is less than or equal to the degree of \(d\), so \(K\) must have degree \(\leq 0\). Therefore, \(K\) is a constant, and so belongs to \(K\). Since \(0 \neq e = kd\), we must have \(k \neq 0\).

We shall prove that any two nonzero polynomials have an hcf by providing a method to calculate one. This method is a generalization of the technique used by Euclid (*Elements*, Book 7, Proposition 2) around 600 BC for calculating hcf's of integers, and is accordingly known as the Euclidean Algorithm.

**Algorithm 3.6 (Euclidean Algorithm)**

*Ingredients*: Two polynomials \(f\) and \(g\) over \(K\), both nonzero.

*Recipe*: For notational convenience let \(f = r_{-1}\), \(g = r_0\). Use the Division Algorithm to find successively polynomials \(q_j\) and \(r_i\) such that

\[
\begin{align*}
r_{-1} &= q_1r_0 + r_1 & \partial r_1 &< \partial r_0 \\
r_0 &= q_2r_1 + r_2 & \partial r_2 &< \partial r_1 \\
r_1 &= q_3r_2 + r_3 & \partial r_3 &< \partial r_2 \\
\cdots \\
&\vdots \\
r_i &= q_{i+2}r_{i+1} + r_{i+2} & \partial r_{i+2} &< \partial r_{i+1}
\end{align*}
\]

(3.1)

Because the degrees of the \(r_i\) decrease, we must eventually reach a point where the process stops; this can happen only if some \(r_{s+2} = 0\). The last equation in the list then reads

\[
r_s = q_{s+2}r_{s+1}
\]

(3.2)

and it provides the answer we seek:

**Theorem 3.7**

With the above notation, \(r_{s+1}\) is an hcf for \(f\) and \(g\).

**Proof** First, we show that \(r_{s+1}\) divides both \(f\) and \(g\). We use descending induction to show that \(r_{s+1} \mid r_i\) for all \(i\). Clearly, \(r_{s+1} \mid r_{s+1}\). Equation (3.2) shows that \(r_{s+1} \mid r_s\),
Equation (3.1) implies that if \( r_{s+1}|r_{i+2} \) and \( r_{s+1}|r_{i+1} \) then \( r_{s+1}|r_i \). Hence \( r_{s+1}|r_i \) for all \( i \); in particular, \( r_{s+1}|r_0 = g \) and \( r_{s+1}|r_{-1} = f \).

Now suppose that \( e|f \) and \( e|g \). By Equation (3.1) and induction, \( e|r_i \) for all \( i \). In particular, \( e|r_{s+1} \). Therefore, \( r_{s+1} \) is an hcf for \( f \) and \( g \), as claimed.

**Example 3.8**
Let \( f = t^4 + 2t^3 + 2t^2 + 2t + 1 \) and \( g = t^2 - 1 \) over \( \mathbb{Q} \). We compute an hcf as follows:

\[
t^4 + 2t^3 + 2t^2 + 2t + 1 = (t^2 + 2t + 3)(t^2 - 1) + 4t + 4
\]
\[
t^2 - 1 = (4t + 4) \left( \frac{1}{4}t - \frac{1}{4} \right)
\]

Hence \( 4t + 4 \) is an hcf. So is any rational multiple of it, in particular, \( t + 1 \).

We end this chapter by deducing from the Euclidean Algorithm an important property of the hcf of two polynomials.

**Theorem 3.9**
Let \( f \) and \( g \) be nonzero polynomials over \( K \), and let \( d \) be an hcf for \( f \) and \( g \). Then there exist polynomials \( a \) and \( b \) over \( K \) such that

\[
d = af + bg
\]

**Proof** Because hcf's are unique up to constant factors, we may assume that \( d = r_{s+1} \) where Equations (3.1) and (3.2) hold. We claim as an induction hypothesis that there exist polynomials \( a_i \) and \( b_i \) such that

\[
d = a_i r_i + b_i r_{i+1}
\]

This is clearly true when \( i = s + 1 \), for we may then take \( a_i = 1, b_i = 0 \). By Equation (3.1)

\[
r_{i+1} = r_{i-1} - q_{i+1}r_i
\]

Hence by induction

\[
d = a_i r_i + b_i (r_{i-1} - q_{i+1}r_i)
\]

so that if we put

\[
a_{i-1} = b_i \quad b_{i-1} = a_i - b_i q_{i+1}
\]

we have

\[
d = a_i \; r_{i-1} + b_i \; r_i
\]
Hence by descending induction
\[ d = a_{-1}r_{-1} + b_{-1}r_0 = af + bg \]
where \( a = a_{-1}, \ b = b_{-1} \). This completes the proof. \( \square \)

The induction step above affords a practical method of calculating \( a \) and \( b \) in any particular case.

### 3.2 Irreducibility

Now we investigate the analogue, for polynomials, of prime numbers. The concept required is irreducibility. In particular, we prove that every polynomial over a subring of \( \mathbb{C} \) can be expressed as a product of irreducibles in an essentially unique way.

An integer is prime if it cannot be expressed as a product of smaller integers. The analogue for polynomials is similar; we interpret smaller as smaller degree. So the following definition yields the polynomial analogue of a prime number.

**Definition 3.10** A polynomial over a subring \( R \) of \( \mathbb{C} \) is reducible if it is a product of two polynomials over \( R \) of smaller degree. Otherwise it is irreducible.

**Examples 3.11**

1. All polynomials of degree 0 or 1 are irreducible, because they certainly cannot be expressed as a product of polynomials of smaller degree.

2. The polynomial \( t^2 - 2 \) is irreducible over \( \mathbb{Q} \). To show this we suppose, for a contradiction, that it is reducible. Then
   \[ t^2 - 2 = (at + b)(ct + d) \]
   where \( a, b, c, d, \in \mathbb{Q} \). Dividing out if necessary we may assume \( a = c = 1 \). Then \( b + d = 0 \) and \( bd = -2 \), so that \( b^2 = 2 \). But no rational number has its square equal to 2 (Exercise 1.2).

3. However, \( t^2 - 2 \) is reducible over the larger subfield \( \mathbb{R} \), for now
   \[ t^2 - 2 = (t - \sqrt{2})(t + \sqrt{2}) \]
   This shows that an irreducible polynomial may become reducible over a larger subfield of \( \mathbb{C} \).

4. The polynomial \( 6t + 3 \) is irreducible in \( \mathbb{Z}[t] \). Although it has factors
   \[ 6t + 3 = 3(2t + 1) \]
the degree of $2t + 1$ is the same as that of $6t + 6$. So this factorization does not count.

5. The constant polynomial 6 is irreducible in $\mathbb{Z}[t]$. Again, $6 = 2 \cdot 3$ does not count.

Any reducible polynomial can be written as the product of two polynomials of smaller degree. If either of these is reducible it, too, can be split up into factors of smaller degree . . . and so on. This process must terminate because the degrees cannot decrease indefinitely. This is the idea behind the proof of:

**Theorem 3.12**

Any nonzero polynomial over a subring $R$ of $\mathbb{C}$ is a product of irreducible polynomials over $R$.

**Proof** Let $g$ be any nonzero polynomial over $R$. We proceed by induction on the degree of $g$. If $\deg g = 0$ or 1, then $g$ is automatically irreducible. If $\deg g > 1$, then either $g$ is irreducible or $g = hk$ where $\deg h, \deg k < \deg g$. By induction, $h$ and $K$ are products of irreducible polynomials, whence $g$ is such a product. The theorem follows by induction.

**Example 3.13**

We can use Theorem 3.12 to prove irreducibility in some cases, especially for cubic polynomials over $\mathbb{Z}$. For instance, let $R = \mathbb{Z}$. The polynomial

$$f(t) = t^3 - 5t + 1$$

is irreducible. If not, then it must have a linear factor $t - \alpha$ over $\mathbb{Z}$, and then $\alpha \in \mathbb{Z}$ and $f(\alpha) = 0$. Moreover, there must exist $\beta, \gamma \in \mathbb{Z}$ such that

$$f(t) = (t - \alpha)(t^2 + \beta t + \gamma)$$

$$= t^3 + (\beta - \alpha)t^2 + (\gamma - \alpha\beta)t - \alpha\gamma$$

so, in particular, $\alpha\gamma = -1$. Therefore, $\alpha = \pm 1$. But $f(1) = -3 \neq 0$ and $f(-1) = 5 \neq 0$. Therefore, no such factor exists.

Irreducible polynomials are analogous to prime numbers. The importance of prime numbers in $\mathbb{Z}$ stems not so much from the possibility of factorizing every integer into primes, but more from the uniqueness (up to order) of the prime factors. Likewise the importance of irreducible polynomials depends upon a uniqueness theorem. Uniqueness of factorization is not obvious, see Stewart and Tall (2002) Chapter 4. In certain cases it is possible to express every element as a product of irreducible elements, without this expression being in any way unique. We shall heed the warning and prove the uniqueness of factorization for polynomials. To avoid technical issues like those in Examples 3.11(4,5), we restrict attention to polynomials over a subfield $K$
of \( \mathbb{C} \). It is possible to prove more general theorems by introducing the idea of a unique factorization domain; see Fraleigh (1989) Chapter 6.

For convenience we make the following:

**Definition 3.14** If \( f \) and \( g \) are polynomials over a subfield \( K \) of \( \mathbb{C} \) with hcf equal to 1, we say that \( f \) and \( g \) are coprime, or \( f \) is prime to \( g \). (The common phrase coprime to is wrong. The prefix 'co' and the 'to' say the same thing, so it is redundant to use both.)

The key to unique factorization is a statement analogous to an important property of primes in \( \mathbb{Z} \), and is used in the same way.

**Lemma 3.15**
Let \( K \) be a subfield of \( \mathbb{C} \), \( f \) an irreducible polynomial over \( K \), and \( g, h \) polynomials over \( K \). If \( f \) divides \( gh \), then either \( f \) divides \( g \) or \( f \) divides \( h \).

**Proof** Suppose that \( f \mid g \). We claim that \( f \) and \( g \) are coprime. For if \( d \) is an hcf for \( f \) and \( g \), then since \( f \) is irreducible and \( d \mid f \), either \( d = k f \) for some \( k \in K \), or \( d = k \in K \). In the first case, \( f \mid g \), contrary to hypothesis. In the second case, 1 is also an hcf for \( f \) and \( g \), so they are coprime. By Theorem 3.9, there exist polynomials \( a \) and \( b \) over \( K \) such that

\[
1 = af + bg
\]

Then

\[
h = haf + hbg
\]

Now \( f \mid haf \), and \( f \mid hbg \) because \( f \mid gh \). Hence \( f \mid h \). This completes the proof.

We may now prove the uniqueness theorem.

**Theorem 3.16**
For any subfield \( K \) of \( \mathbb{C} \), factorization of polynomials over \( K \) into irreducible polynomials is unique up to constant factors and the order in which the factors are written.

**Proof** Suppose that \( f = f_1 \ldots f_r = g_1 \ldots g_s \), where \( f \) is a polynomial over \( K \) and \( f_1, \ldots, f_r, g_1, \ldots, g_s \) are irreducible polynomials over \( K \). If all the \( f_i \) are constant, then \( f \in K \), so all the \( g_j \) are constant. Otherwise, we may assume that no \( f_i \) is constant by dividing out all of the constant terms. Then \( f_i \mid g_j \ldots g_s \). By an obvious induction based on Lemma 3.15, \( f_i \mid g_j \) for some \( j \). We can choose notation so that \( j = 1 \), and then \( f_i \mid g_1 \). Because \( f_i \) and \( g_1 \) are irreducible and \( f_i \) is not a constant, we must have \( f_i = k_1 g_1 \) for some constant \( k_1 \). Similarly \( f_2 = k_2 g_2, \ldots, f_r = k_r g_r \) where \( k_2, \ldots, k_r \) are constant. The remaining \( g_l \) (\( l > r \)) must also be constant, or else the degree of the right-hand side would be too large. The theorem is proved.
3.3 Gauss’s Lemma

It is in general very difficult to decide — without using computer algebra, at any rate — whether a given polynomial is irreducible. As an example, think about

\[ t^{16} + t^{15} + t^{14} + t^{13} + t^{12} + t^{11} + t^{10} + t^{9} + t^{8} + t^{7} + t^{6} + t^{5} + t^{4} + t^{3} + t^{2} + t + 1 \]

This is not an idle example; we shall be considering precisely this polynomial in Chapter 19 in connection with the regular 17-gon, and its irreducibility (or not) will be crucial.

To test for irreducibility by trying all possible factors is usually futile. Indeed, at first sight there are infinitely many potential factors to try, although with suitable short cuts the possibilities can be reduced to a finite, usually unfeasibly large, number. The resulting method can be applied, in principle, to polynomials over \( \mathbb{Q} \), for example. See van der Waerden (1953); Garling (1960). Even then, the method is not really practicable.

Instead, we have to invent a few useful tricks. In the next two sections we describe two of them: Eisenstein’s Criterion and reduction modulo a prime. Both tricks apply in the first instance to polynomials over \( \mathbb{Z} \). However, it is known that irreducibility over \( \mathbb{Z} \) is equivalent to irreducibility over \( \mathbb{Q} \). This was proved by Gauss, and it is an extremely useful result which we use repeatedly.

**Lemma 3.17 (Gauss’s Lemma)**

*Let \( f \) be a polynomial over \( \mathbb{Z} \) that is irreducible over \( \mathbb{Z} \). Then \( f \), considered as a polynomial over \( \mathbb{Q} \), is also irreducible over \( \mathbb{Q} \).*

**Proof** The point of this lemma is that when we extend the subring of coefficients from \( \mathbb{Z} \) to \( \mathbb{Q} \), there are hosts of new polynomials which, perhaps, might be factors of \( f \). We show that in fact they are not. So we suppose that \( f \) is irreducible over \( \mathbb{Z} \) but reducible over \( \mathbb{Q} \), so that \( f = gh \) where \( g \) and \( h \) are polynomials over \( \mathbb{Q} \), of smaller degree, and seek a contradiction. Multiplying through by the product of the denominators of the coefficients of \( g \) and \( h \), we can rewrite this equation in the form \( nf = g'h' \), where \( n \in \mathbb{Z} \) and \( g', h' \) are polynomials over \( \mathbb{Z} \). We now show that we can cancel out the prime factors of \( n \) one by one, without going outside \( \mathbb{Z}[t] \).

Suppose that \( p \) is a prime factor of \( n \). We claim that if

\[ g' = g_0 + g_1 t + \cdots + g_r t^r \quad \text{and} \quad h' = h_0 + h_1 t + \cdots + h_s t^s \]

then either \( p \) divides all the coefficients \( g_i \), or else \( p \) divides all the coefficients \( h_j \).

If not, there must be smallest values \( i \) and \( j \) such that \( p \nmid g_i \) and \( p \nmid h_j \). However, \( p \nmid g_i \) and 

\[ t^{16} + t^{15} + t^{14} + t^{13} + t^{12} + t^{11} + t^{10} + t^{9} + t^{8} + t^{7} + t^{6} + t^{5} + t^{4} + t^{3} + t^{2} + t + 1 \]
divides the coefficient of \( t^{i+j} \) in \( g'h' \), which is

\[ h_0 g_{i+j} + h_1 g_{i+j-1} + \cdots + h_j g_i + \cdots + h_{i+j} g_0 \]

and by the choice of \( i \) and \( j \), the prime \( p \) divides every term of this expression except perhaps \( h_j g_i \). But \( p \) divides the whole expression, so \( p | h_j g_i \). However, \( p \nmid h_j \) and \( p \nmid g_i \), a contradiction. This establishes the claim.

Without loss of generality, we may assume that \( p \) divides every coefficient \( g_i \). Then \( g' = pg'' \) where \( g'' \) is a polynomial over \( \mathbb{Z} \) of the same degree as \( g' \) (or \( g \)). Let \( n = pn_1 \). Then \( pn_1 f = pg''h' \), so that \( n_1 f = g''h' \). Proceeding in this way we can remove all the prime factors of \( n \), arriving at an equation \( f = \tilde{g}\tilde{h} \). Here \( \tilde{g} \) and \( \tilde{h} \) are polynomials over \( \mathbb{Z} \), which are rational multiples of the original \( g \) and \( h \), so \( \partial \tilde{g} = \partial g \) and \( \partial \tilde{h} = \partial h \). But this contradicts the irreducibility of \( f \) over \( \mathbb{Z} \), so the lemma is proved.

\[ \square \]

**COROLLARY 3.18**

Let \( f \in \mathbb{Z}[t] \) and suppose that over \( \mathbb{Q}[t] \) there is a factorization into irreducibles:

\[ f = g_1 \cdots g_s \]

Then there exist \( a_i \in \mathbb{Q} \) such that \( a_ig_i \in \mathbb{Z}[t] \) and \( a_1 \ldots a_s = 1 \). Furthermore,

\[ f = (a_1g_1) \cdots (a_sg_s) \]

is a factorization of \( f \) into irreducibles in \( \mathbb{Z}[t] \).

**PROOF** Factorize \( f \) into irreducibles over \( \mathbb{Z}[t] \), obtaining \( f = h_1 \ldots h_r \). By Gauss’s Lemma, each \( h_j \) is irreducible over \( \mathbb{Q} \). By uniqueness of factorization in \( \mathbb{Q}[t] \), we must have \( r = s \) and \( h_j = a_jg_j \) for \( a_j \in \mathbb{Q} \). Clearly, \( a_1 \ldots a_s = 1 \). The corollary is now proved.

\[ \square \]

### 3.4 Eisenstein’s Criterion

No, not Einstein. Ferdinand Gotthold Eisenstein was a student of Gauss, and greatly impressed his tutor. We can apply the tutor’s lemma to prove the student’s criterion for irreducibility.

**THEOREM 3.19 (Eisenstein’s Criterion)**

Let

\[ f(t) = a_0 + a_1t + \cdots + a_nt^n \]

be a polynomial over \( \mathbb{Z} \). Suppose that there is a prime \( q \) such that
3.4 Eisenstein’s Criterion

1. \( q \nmid a_n \)
2. \( q \mid a_i \) (\( i = 0, \ldots, n - 1 \))
3. \( q^2 \nmid a_0 \)

Then \( f \) is irreducible over \( \mathbb{Q} \).

**Proof**  By Gauss’s Lemma, it is sufficient to show that \( f \) is irreducible over \( \mathbb{Z} \). Suppose for a contradiction that \( f = gh \), where

\[
g = b_0 + b_1 t + \cdots + b_r t^r \\
h = c_0 + c_1 t + \cdots + c_s t^s
\]

are polynomials of smaller degree over \( \mathbb{Z} \). Then \( r \geq 1, s \geq 1 \), and \( r + s = n \). Now \( b_0 c_0 = a_0 \) so by (2) \( q \mid b_0 \) or \( q \mid c_0 \). By (3) \( q \) cannot divide both \( b_0 \) and \( c_0 \), so without loss of generality we can assume \( q \mid b_0 \), \( q \nmid c_0 \). If all \( b_j \) are divisible by \( q \), then \( a_n \) is divisible by \( q \), contrary to Condition (1) above. Let \( b_j \) be the first coefficient of \( g \) not divisible by \( q \). Then

\[
a_j = b_j c_0 + \cdots + b_0 c_j
\]

where \( j < n \). This implies that \( q \) divides \( c_0 \), because \( q \) divides \( a_i, b_0, \ldots, b_{i-1} \), but not \( b_j \). This is a contradiction. Hence \( f \) is irreducible.

**Examples 3.20**

1. Consider

\[
f(t) = \frac{2}{9} t^5 + \frac{5}{3} t^4 + t^3 + \frac{1}{3} \quad \text{over } \mathbb{Q}
\]

This is irreducible over \( \mathbb{Q} \) if and only if

\[
9f(t) = 2t^5 + 15t^4 + 9t^3 + 3
\]

is irreducible over \( \mathbb{Q} \). Eisenstein’s criterion now applies with \( q = 3 \), showing that \( f \) is irreducible.

2. Consider

\[
f(t) = t^{16} + t^{15} + \cdots + 1
\]

as mentioned above. As it stands, \( f \) is not susceptible to the Eisenstein treatment. But \( f(t) \) is obviously irreducible if and only if \( f(t + 1) \) is irreducible.
(Hint: \( f(t) = g(t)h(t) \) if and only if \( f(t + 1) = g(t + 1)h(t + 1) \).) If we expand this monster, we obtain

\[
f(t + 1) = t^{16} + 17t^{15} + 136t^{14} + 680t^{13} + 2380t^{12} + 6188t^{11}
+ 12376t^{10} + 19448t^9 + 24310t^8 + 24310t^7 + 19448t^6
+ 12376t^5 + 6188t^4 + 2380t^3 + 680t^2 + 136t + 17
\]

\[
equiv t^{16} + 17(t^{15} + 8t^{14} + 40t^{13} + 140t^{12} + 364t^{11} + 728t^{10}
+ 1144t^9 + 1430t^8 + 1430t^7 + 1144t^6 + 728t^5 + 364t^4
+ 140t^3 + 40t^2 + 8t + 1) \quad (3.3)
\]

Therefore, Eisenstein's criterion applies with \( q = 17 \), so \( f \) is irreducible over \( \mathbb{Q} \). There is, incidentally, a good reason why this method works here, which does not emerge clearly from direct calculations. See Lemma 13 for details.

---

### 3.5 Reduction Modulo \( p \)

A second trick to prove irreducibility of polynomials is that \( \mathbb{Z}[t] \) involves reducing the polynomial modulo a prime integer \( p \).

Recall that if \( n \in \mathbb{Z} \), two integers \( a, b \) are congruent modulo \( n \), written

\[
a \equiv b \pmod{n}
\]

if \( a - b \) is divisible by \( n \). The number \( n \) is the modulus, and "modulo" is Latin for "to the modulus". Congruence modulo \( n \) is an equivalence relation, and the set of equivalence classes is denoted by \( \mathbb{Z}_n \). Arithmetic in \( \mathbb{Z}_n \) is just like arithmetic in \( \mathbb{Z} \), except that \( n \equiv 0 \).

Under addition, \( \mathbb{Z}_n \) is a cyclic group of order \( n \). Indeed, this is a standard way to define cyclic group.

The multiplicative structure of \( \mathbb{Z}_n \) is more interesting. For some values of \( n \), there are elements that do not have (multiplicative) inverses — consider \( 2 \in \mathbb{Z}_6 \), for example. It is easy to see that \( a \in \mathbb{Z}_n \) has an inverse if and only if \( a \) is prime to \( n \).

**Definition 3.21** The group of units \( \mathbb{Z}_n^* \) of \( \mathbb{Z}_n \) consists of the elements \( a \in \mathbb{Z}_n \) such that \( 1 \leq a \leq n \) and \( a \) is prime to \( n \) under the operation of multiplication.

The order of this group is given by an important arithmetical function.

**Definition 3.22** The Euler function \( \phi(n) \) is the number of integers \( a \), with \( 1 \leq a \leq n - 1 \), such that \( a \) is prime to \( n \).
3.5 Reduction Modulo \( p \)

Definition 3.22 implies immediately that the order of \( \mathbb{Z}_n^* \) is equal to \( \phi(n) \). The Euler function \( \phi(n) \) has numerous interesting properties. In particular,

\[
\phi(p^k) = (p - 1)p^{k-1}
\]

if \( p \) is prime, and

\[
\phi(r)\phi(s) = \phi(rs)
\]

when \( r, s \) are coprime (see Exercise 3.1).

The test for irreducibility that we now wish to discuss is most easily explained by an example. The idea is this. There is a natural map \( \mathbb{Z} \to \mathbb{Z}_n \) in which each \( m \in \mathbb{Z} \) maps to its congruence class modulo \( n \). The natural map extends in an obvious way to a map \( \mathbb{Z}[t] \to \mathbb{Z}_n[t] \). Now a reducible polynomial over \( \mathbb{Z} \) is a product \( gh \) of polynomials of lower degree, and this factorization is preserved by the map. Provided \( n \) does not divide the highest coefficient of the given polynomial, the image is irreducible over \( \mathbb{Z}_n \). So if the image of a polynomial is irreducible over \( \mathbb{Z}_n \), then the original polynomial must be irreducible over \( \mathbb{Z} \). (The corresponding statement for reducible polynomials is in general false; consider \( t^2 - 2 \in \mathbb{Q}[t] \) when \( p = 2 \).)

Since \( \mathbb{Z}_n \) is finite, there are only finitely many possibilities to check when deciding irreducibility.

In practice, the trick is to choose the right value for \( n \).

**Example 3.23**

Consider

\[
f(t) = t^4 + 15t^2 + 7 \text{ over } \mathbb{Z}
\]

Over \( \mathbb{Z}_5 \) this becomes \( t^4 + 2 \). If this is reducible over \( \mathbb{Z}_5 \), then either it has a factor of degree 1, or it is a product of two factors of degree 2. The first possibility gives rise to an element \( x \in \mathbb{Z}_5 \) such that \( x^4 + 2 = 0 \). No such element exists (there are only five elements to check) so this case is ruled out. In the remaining case we have, without loss of generality,

\[
t^4 + 2 = (t^2 + at + b)(t^2 + ct + d)
\]

Therefore, \( a + c = 0 \), \( ac + b + d = 0 \), \( bd = 2 \). Thus, \( b + d = a^2 \) which can take only the values 0, 1, 4 because these are the only squares in \( \mathbb{Z}_5 \). Hence, either \( b(1 - b) = 2 \) or \( -b^2 = 2 \) or \( b(4 - b) = 2 \). Trying all possible values 0, 1, 2, 3, 4 for \( b \) we see that none of these equations can hold. Hence, \( t^4 + 2 \) is irreducible over \( \mathbb{Z}_5 \) and, therefore, the original \( f(t) \) is irreducible over \( \mathbb{Z}_5 \) and hence over \( \mathbb{Q} \).

Notice that if instead we try to work in \( \mathbb{Z}_3 \), then \( f(t) \) becomes \( t^4 + 1 \), which equals \( (t^2 + t - 1)(t^2 - t - 1) \) and so is reducible. Thus working (mod 3) fails to prove irreducibility.
3.6 Zeros of Polynomials

We have already studied the zeros of a polynomial over \( \mathbb{C} \). It will be useful to employ similar terminology for polynomials over a subring \( R \) of \( \mathbb{C} \), because then we can keep track of where the zeros lie. We begin with a formal definition.

**Definition 3.24** Let \( R \) be a subring of \( \mathbb{C} \), and let \( f \) be a polynomial over \( R \). An element \( \alpha \in R \) such that \( f(\alpha) = 0 \) is a zero of \( f \) in \( R \).

To illustrate some basic phenomena associated with zeros, we consider polynomials over the real numbers. In this case, we can draw the graph \( y = f(x) \) (in standard terminology, with \( x \in \mathbb{R} \) in place of \( i \)). The graph might, for example, resemble Figure 3.1.

The zeros of \( f \) are the values of \( x \) at which the curve crosses the \( x \)-axis. Consider the three zeros marked A, B, C in the diagram. At A the curve cuts straight through the axis; at B it bounces off it; at C it slides through horizontally. These phenomena are generally distinguished by saying that B and C are multiple zeros of \( f(t) \). The single zero B must be thought of as two equal zeros (or more) and C as three (or more).

But if they are equal, how can there be two of them? The answer is the concept of multiplicity of a zero introduced in Section 2.3. We now reformulate this concept without using the Fundamental Theorem of Algebra, which in this context is the proverbial nutcracking sledgehammer. The key is to look at linear factors of \( f \).

**Lemma 3.25**
Let \( f \) be a polynomial over the subfield \( K \) of \( \mathbb{C} \). An element \( \alpha \in K \) is a zero of \( f \) if and only if \((t - \alpha)|f(t)\) in \( K[t] \).

**Proof** We know that \((t - \alpha)|f(t)\) in \( \mathbb{C}[t] \) by Theorem 2.8, but we want slightly more. If \((t - \alpha)|f(t)\) in \( K[t] \), then \( f(t) = (t - \alpha)g(t) \) for some polynomial \( g \) over \( K \), so that \( f(\alpha) = (\alpha - \alpha)g(\alpha) = 0 \).

![Figure 3.1: Multiple zeros of a (real) polynomial. The multiplicity is 1 at (A), 2 at (B), and 3 at (C).](image-url)
3.6 Zeros of Polynomials

Conversely, suppose \( f(\alpha) = 0 \). By the Division Algorithm, there exist polynomials \( q, r \in K[t] \) such that

\[
f(t) = (t - \alpha)q(t) + r(t)
\]

where \( \partial r < 1 \). Thus, \( r(t) = r \in K \). Substituting \( \alpha \) for \( t \),

\[
0 = f(\alpha) = (\alpha - \alpha)q(\alpha) + r
\]

so \( r = 0 \). Hence, \( (t - \alpha)|f(t) \in K[t] \) as required.

We can now say what we mean by a multiple zero, without appealing to the Fundamental Theorem of Algebra.

**Definition 3.26** Let \( f \) be a polynomial over the subfield \( K \) of \( \mathbb{C} \). An element \( \alpha \in K \) is a simple zero of \( f \) if \( (t - \alpha)|f(t) \) but \( (t - \alpha)^2 \nmid f(t) \). The element \( \alpha \) is a zero of \( f \) of multiplicity \( m \) if \( (t - \alpha)^m|f(t) \) but \( (t - \alpha)^{m+1} \nmid f(t) \). Zeros of multiplicity greater than 1 are repeated or multiple zeros.

For example, \( t^3 - 3t + 2 \) over \( \mathbb{Q} \) has zeros at \( \alpha = 1, -2 \). It factorizes as \( (t - 1)^2(t + 2) \). Hence, \(-2\) is a simple zero, while \( 1 \) is a zero of multiplicity \( 2 \).

When \( K = \mathbb{R} \) and we draw a graph, as in Figure 1.1, points like A are the simple zeros; points like B are zeros of even multiplicity; and points like C are zeros of odd multiplicity \( \geq 1 \). For subfields of \( \mathbb{C} \) other than \( \mathbb{R} \) (except perhaps \( \mathbb{Q} \), or other subfields of \( \mathbb{R} \)) a graph has no evident meaning, but the simple geometric picture for \( \mathbb{R} \) is often helpful.

**Lemma 3.27**

Let \( f \) be a nonzero polynomial over the subfield \( K \) of \( \mathbb{C} \), and let its distinct zeros be \( \alpha_1, \ldots, \alpha_r \) with multiplicities \( m_1, \ldots, m_r \), respectively. Then

\[
f(t) = (t - \alpha_1)^{m_1} \ldots (t - \alpha_r)^{m_r} g(t)
\]  \( (3.4) \)

where \( g \) has no zeros in \( K \).

Conversely, if Equation \( (3.4) \) holds and \( g \) has no zeros in \( K \), then the zeros of \( f \) in \( K \) are \( \alpha_1, \ldots, \alpha_r \), with multiplicities \( m_1, \ldots, m_r \), respectively.

**Proof** For any \( \alpha \in K \) the polynomial \( t - \alpha \) is irreducible. Hence, for distinct \( \alpha, \beta \in K \) the polynomials \( t - \alpha \) and \( t - \beta \) are coprime in \( K[t] \). By uniqueness of factorization (Theorem 2.3) Equation \( (3.4) \) must hold. Moreover, \( g \) cannot have any zeros in \( K \), or else \( f \) would have extra zeros or zeros of larger multiplicity.

The converse follows easily from uniqueness of factorization.

From this lemma we deduce a famous theorem
THEOREM 3.28
The number of zeros of a polynomial over a subfield of $\mathbb{C}$, counted according to multiplicity, is less than or equal to its degree.

PROOF In Equation (3.4) we must have $m_1 + \cdots + m_r \leq \partial f$.

Exercises

3.1 For the following pairs of polynomials $f$ and $g$ over $\mathbb{Q}$, find the quotient and remainder on dividing $g$ by $f$.
   a. $g = t^7 - t^3 + 5, \quad f = t^3 + 7$
   b. $g = t^2 + 1, \quad f = t^2$
   c. $g = 4t^3 - 17t^2 + t - 3, \quad f = 2t + 5$
   d. $g = t^4 - 1, \quad f = t^2 + 1$
   e. $g = t^4 - 1, \quad f = 3t^2 + 3t$

3.2 Find hcf's for these pairs of polynomials, and check that your results are common factors of $f$ and $g$.

3.3 Express these hcf's in the form $af + bg$.

3.4 Decide the irreducibility or otherwise of the following polynomials:
   a. $t^4 + 1$ over $\mathbb{R}$
   b. $t^4 + 1$ over $\mathbb{Q}$
   c. $t^7 + 11t^3 - 33t + 22$ over $\mathbb{Q}$
   d. $t^3 + t^2 + t + 1$ over $\mathbb{Q}$
   e. $t^3 - 7t^2 + 3t + 3$ over $\mathbb{Q}$

3.5 Decide the irreducibility or otherwise of the following polynomials:
   a. $t^4 + t^3 + t^2 + t + 1$ over $\mathbb{Q}$ (Hint: Substitute $t + 1$ in place of $t$ and appeal to Eisenstein's Criterion.)
   b. $t^5 + t^4 + t^3 + t^2 + t + 1$ over $\mathbb{Q}$
   c. $t^6 + t^5 + t^4 + t^3 + t^2 + t + 1$ over $\mathbb{Q}$

3.6 In each of the above cases, factorize the polynomial into irreducibles.

3.7 Say that a polynomial $f$ over a subfield $K$ of $\mathbb{C}$ is prime if whenever $f|gh$ either $f|g$ or $f|h$. Show that a polynomial $f \neq 0$ is prime if and only if it is irreducible.
3.8 Find the zeros of the following polynomials; first over \(\mathbb{Q}\), then \(\mathbb{R}\), then \(\mathbb{C}\).

a. \(t^3 + 1\)

b. \(t^3 - 6t^2 + 11t - 6\)

c. \(t^5 + t + 1\)

d. \(t^2 + 1\)

e. \(t^4 + t^3 + t^2 + t + 1\)

f. \(t^4 - 6t^2 + 11\)

3.9 Let \(\phi(n)\) be the Euler function. Prove that

\[
\phi(p^k) = (p - 1)p^{k-1}
\]

if \(p\) is prime, and

\[
\phi(r)\phi(s) = \phi(rs)
\]

when \(r, s\) are coprime. Deduce a formula for \(\phi(n)\) in terms of the prime factorization of \(n\).

3.10 Prove that

\[
\phi(n) = n \prod_{\substack{p \text{ prime} \ 2 \mid n}} \left(1 - \frac{1}{p}\right)
\]

3.11 If \(a\) is prime to \(n\), where both are integers, prove that \(a^{\phi(n)} \equiv 1 \pmod{n}\).

3.12 Prove that for any \(m \in \mathbb{N}\) the equation \(\phi(n) = m\) has only finitely many solutions \(n\). Find examples to show that there may be more than one solution.

3.13 Guess and prove a formula for \(\sum_{d \mid n} \phi(d)\).

3.14 If \(n\) is odd, prove that \(\phi(4n) = 2\phi(n)\).

3.15 Check that

\[
1 + 2 = \frac{3}{2}\phi(3)
\]

\[
1 + 3 = \frac{4}{2}\phi(4)
\]

\[
1 + 2 + 3 + 4 = \frac{5}{2}\phi(5)
\]

\[
1 + 5 = \frac{6}{2}\phi(6)
\]

\[
1 + 2 + 3 + 4 + 5 + 6 = \frac{7}{2}\phi(7)
\]

What is the theorem? Prove it.
3.16* Prove that if \( g \in \mathbb{Z}_{24} \) then \( g^2 = 1 \), so \( g \) has order 2 or is the identity. Show that 24 is the largest value of \( n \) for which every nonidentity element of \( \mathbb{Z}_n \) has order 2. Which are the others?

3.17 Mark the following true or false. (Here polynomial means polynomial over \( \mathbb{C} \).)

   a. Every polynomial of degree \( n \) has \( n \) distinct zeros.
   b. Every polynomial of degree \( n \) has at most \( n \) distinct zeros.
   c. Every polynomial of degree \( n \) has at least \( n \) distinct zeros.
   d. If \( f, g \) are nonzero polynomials and \( f \) divides \( g \), then \( \partial f < \partial g \).
   e. If \( f, g \) are nonzero polynomials and \( f \) divides \( g \), then \( \partial f \leq \partial g \).
   f. Every polynomial of degree 1 is irreducible.
   g. Every irreducible polynomial has prime degree.
   h. If a polynomial \( f \) has integer coefficients and is irreducible over \( \mathbb{Z} \), then it is irreducible over \( \mathbb{Q} \).
   i. If a polynomial \( f \) has integer coefficients and is irreducible over \( \mathbb{Z} \), then it is irreducible over \( \mathbb{R} \).
   j. If a polynomial \( f \) has integer coefficients and is irreducible over \( \mathbb{R} \), then it is irreducible over \( \mathbb{Z} \).
Chapter 4

Field Extensions

Galois’s original theory was couched in terms of polynomials over the complex field. The modern approach is a consequence of the methods used, starting around 1890 and flourishing in the 1920s and 1930s, to generalize the theory to arbitrary fields. From this viewpoint the central object of study ceases to be a polynomial, and becomes instead a field extension related to a polynomial. Every polynomial \( f \) over a field \( K \) defines another field \( L \) containing \( K \) (or at any rate a subfield isomorphic to \( K \)). There are conceptual advantages in setting up the theory from this point of view. In this chapter we define field extensions (always working inside \( \mathbb{C} \)) and explain the link with polynomials.

4.1 Field Extensions

Suppose that we wish to study the quartic polynomial

\[
f(t) = t^4 - 4t^2 + 5
\]

over \( \mathbb{Q} \). Its irreducible factorization over \( \mathbb{Q} \) is

\[
f(t) = (t^2 + 1)(t^2 - 5)
\]

so the zeros of \( f \) in \( \mathbb{C} \) are \( \pm i \) and \( \pm \sqrt{5} \). There is a natural subfield \( L \) of \( \mathbb{C} \) associated with these zeros; in fact, it is the unique smallest subfield that contains them. We claim that \( L \) consists of all complex numbers of the form

\[
p + qi + r\sqrt{5} + si\sqrt{5} \quad (p, q, r, s \in \mathbb{Q})
\]

Clearly, \( L \) must contain every such element, and it is not hard to see that sums and products of such elements have the same form. It is harder to see that inverses of (nonzero) such elements also have the same form, but it is true. We postpone the proof to Example 4.8. Thus the study of a polynomial over \( \mathbb{Q} \) leads us to consider a subfield \( L \) of \( \mathbb{C} \) that contains \( \mathbb{Q} \). In the same way, the study of a polynomial over an arbitrary subfield \( K \) of \( \mathbb{C} \) will lead to a subfield \( L \) of \( \mathbb{C} \) that contains \( K \). We shall call \( L \) an extension of \( K \). For technical reasons this definition is too restrictive; we wish to allow cases where \( L \) contains a subfield isomorphic to \( K \), but not necessarily equal to it.
**Definition 4.1** A field extension is a monomorphism \( \nu : K \to L \), where \( K \) and \( L \) are subfields of \( \mathbb{C} \). We say that \( K \) is the small field and \( L \) is the large field.

Notice that with a strict set theoretic definition of function, the map \( \nu \) determines both \( K \) and \( L \) (see the definition of monomorphism). We often think of a field extension as being a pair of fields \((K, L)\) when it is clear which monomorphism is intended.

**Example 4.2**

1. The inclusion maps \( \nu_1 : \mathbb{Q} \to \mathbb{R}, \nu_2 : \mathbb{R} \to \mathbb{C} \), and \( \nu_3 : \mathbb{Q} \to \mathbb{C} \) are all field extensions.

2. Let \( K \) be the set of all real numbers of the form \( p + q\sqrt{2} \), where \( p, q \in \mathbb{Q} \). Then \( K \) is a subfield of \( \mathbb{C} \) by Example 1.4. The inclusion map \( \nu : \mathbb{Q} \to K \) is a field extension.

If \( \nu : K \to L \) is a field extension, then we can usually identify \( K \) with its image \( \nu(K) \), so that \( \nu \) can be thought of as an inclusion map and \( K \) can be thought of as a subfield of \( L \). Under these circumstances we use the notation

\[
L : K
\]

for the extension, and say that \( L \) is an extension of \( K \). In the future we shall identify \( K \) and \( \nu(K) \) whenever this is legitimate.

The next concept is one which pervades much of abstract algebra.

**Definition 4.3** Let \( X \) be a subset of \( \mathbb{C} \). Then the subfield of \( \mathbb{C} \) generated by \( X \) is the intersection of all subfields of \( \mathbb{C} \) that contain \( X \).

It is easy to see that this definition is equivalent to either of the following.

1. The (unique) smallest subfield of \( \mathbb{C} \) that contains \( X \).

2. The set of all elements of \( \mathbb{C} \) that can be obtained from elements of \( X \) by a finite sequence of field operations, provided \( X \neq \{0\} \) or \( \emptyset \).

**Proposition 4.4**

Every subfield of \( \mathbb{C} \) contains \( \mathbb{Q} \).

**Proof** Let \( K \subseteq \mathbb{C} \) be a subfield. Then 0, 1 \( \in K \) by definition, so inductively we find that \( 1 + \cdots + 1 = n \) lies in \( K \) for every integer \( n > 0 \). Now \( K \) is closed under additive inverses, so \(-n\) also lies in \( K \), proving that \( \mathbb{Z} \subseteq K \). Finally, if \( p, q \in \mathbb{Z} \) and \( q \neq 0 \), closure under products and multiplicative inverses shows that \( pq^{-1} \in K \). Therefore, \( \mathbb{Q} \subseteq K \) as claimed.
4.1 Field Extensions

**Corollary 4.5**
Let $X$ be a subset of $\mathbb{C}$. Then the subfield of $\mathbb{C}$ generated by $X$ contains $\mathbb{Q}$.

Because of Corollary 4.5, we use the notation

$$\mathbb{Q}(X)$$

for the subfield of $\mathbb{C}$ generated by $X$.

**Example 4.6**
We shall find the subfield $K$ of $\mathbb{C}$ generated by $X = \{1, i\}$. By Proposition 4.4, $K$ must contain $\mathbb{Q}$. Since $K$ is closed under the arithmetical operations, it must contain all complex numbers of the form $p + qi$, where $p, q \in \mathbb{Q}$. Let $M$ be the set of all such numbers. We claim that $M$ is a subfield of $\mathbb{C}$. Clearly, $M$ is closed under sums, differences, and products. Further,

$$(p + qi)^{-1} = \frac{p}{p^2 + q^2} - \frac{q}{p^2 + q^2}i$$

so that every nonzero element of $M$ has a multiplicative inverse in $M$. Hence $M$ is a subfield, and contains $X$. Because $K$ is the smallest subfield containing $X$, we have $K \subseteq M$. But $M \subseteq K$ by definition. Hence $K = M$, and we have found a description of the subfield generated by $X$.

In the case of a field extension $L : K$, we are mainly interested in subfields lying between $K$ and $L$. This means that we can restrict attention to subsets $X$ that contain $K$ equivalently to sets of the form $K \cup Y$ where $Y \subseteq L$.

**Definition 4.7** If $L : K$ is a field extension and $Y$ is a subset of $L$, then the subfield of $\mathbb{C}$ generated by $K \cup Y$ is written $K(Y)$ and is said to be obtained from $K$ by adjoining $Y$.

Clearly, $K(Y) \subseteq L$ since $L$ is a subfield of $\mathbb{C}$. Notice that $K(Y)$ is in general considerably larger than $K \cup Y$.

This notation is open to all sorts of useful abuses. If $Y$ has a single element $y$ we write $K(y)$ instead of $K(\{y\})$, and in the same spirit, $K(y_1, \ldots, y_n)$ will replace $K(\{y_1, \ldots, y_n\})$.

**Example 4.8**
Let $K = \mathbb{Q}$ and let $Y = \{i, \sqrt{5}\}$. Then $K(Y)$ must contain $K$ and $Y$. It also contains the product $i\sqrt{5}$. Because $K \supseteq \mathbb{Q}$, the subfield $K(Y)$ must contain all elements

$$\alpha = p + qi + r\sqrt{5} + si\sqrt{5} \quad (p, q, r, s \in \mathbb{Q}).$$

Let $L \subseteq \mathbb{C}$ be the set of all such $\alpha$. If we prove that $L$ is a subfield of $\mathbb{C}$, then it follows that $K(Y) = L$. Moreover, $L$ is a subfield of $\mathbb{C}$ if and only if for $\alpha \neq 0$ we can find an
inverse \( \alpha^{-1} \in L \). If fact, we shall prove that if \((p, q, r, s) \neq (0, 0, 0, 0)\) then \(\alpha \neq 0\), and then

\[ (p + qi + r\sqrt{5} + si\sqrt{5})^{-1} \in L \]

First, suppose that \(p + qi + r\sqrt{5} + s\sqrt{5} = 0\). Then

\[ p + r\sqrt{5} = -i(q + s\sqrt{5}) \]

Now both \(p + r\sqrt{5}\) and \(-(q + s\sqrt{5})\) are real, but \(i\) is imaginary. Therefore, \(p + r\sqrt{5} = 0\) and \(q + s\sqrt{5} = 0\). If \(r \neq 0\) then \(\sqrt{5} = -p/r \in \mathbb{Q}\), but \(\sqrt{5}\) is irrational. Therefore, \(r = 0\), whence \(p = 0\). Similarly, \(q = s = 0\).

Now we prove the existence of \(\alpha^{-1}\) in two stages. Let \(M\) be the subset of \(L\) containing all \(p + qi\) \((p, q \in \mathbb{Q})\). Then we can write

\[ \alpha = x + y\sqrt{5} \]

where \(x = p + iq\) and \(y = r + is \in M\). Let

\[ \beta = p + qi - r\sqrt{5} - si\sqrt{5} = x - y\sqrt{5} \in L \]

Then

\[ \alpha \beta = (x + y\sqrt{5})(x - y\sqrt{5}) = x^2 - 5y^2 = z \]

say, where \(z \in M\). Because \(\alpha \neq 0\) and \(\beta \neq 0\), we have \(z \neq 0\), so \(\alpha^{-1} = \beta z^{-1}\). Now write \(z = u + vi\) \((u, v \in \mathbb{Q})\) and consider \(w = u - vi\). Since \(zw = u^2 + v^2 \in \mathbb{Q}\) we have

\[ z^{-1} = (u^2 + v^2)^{-1} w \in M \]

so \(\alpha^{-1} = \beta z^{-1} \in L\).

Alternatively, we can obtain an explicit formula by working out the expression

\[ (p + qi + r\sqrt{5} + si\sqrt{5})(p - qi + r\sqrt{5} - si\sqrt{5}) \]

\times \( (p + qi - r\sqrt{5} - si\sqrt{5})(p - qi - r\sqrt{5} + si\sqrt{5}) \)

and showing that it belongs to \(\mathbb{Q}\), and then dividing by

\[ (p + qi + r\sqrt{5} + si\sqrt{5}) \]

(see Exercise 4.6.)

**Examples 4.9**

1. The subfield \(\mathbb{R}(i)\) of \(\mathbb{C}\) must contain all elements \(x + iy\) where \(x, y \in \mathbb{R}\). But those elements comprise the whole of \(\mathbb{C}\). Therefore, \(\mathbb{C} = \mathbb{R}(i)\).

2. The subfield \(P\) of \(\mathbb{R}\) consisting of all numbers \(p + q\sqrt{2}\) where \(p, q \in \mathbb{Q}\) is easily seen to equal \(\mathbb{Q}((\sqrt{2}))\).
3. It is not always true that a subfield of the form $K(\alpha)$ consists of all elements of the form $j + k\alpha$ where $j, k \in K$. It certainly contains all such elements, but they need not form a subfield.

For example, in $\mathbb{R} : \mathbb{Q}$ let $\alpha$ be the real cube root of 2, and consider $\mathbb{Q}(\alpha)$. As well as $\alpha$, the subfield $\mathbb{Q}(\alpha)$ must contain $\alpha^2$. We show that $\alpha^2 \neq j + k\alpha$ for $j, k \in \mathbb{Q}$. For a contradiction, suppose that $\alpha^2 = j + k\alpha$. Then $2 - \alpha^2 = j\alpha + k\alpha^2 - jk + (j + k^2)\alpha$. Therefore, $(j + k^2)\alpha = 2 - jk$. Since $\alpha$ is irrational, $(j + k^2) = 0 = 2 - jk$. Eliminating $j$, we find that $k^2 = 2$, contrary to $k \in \mathbb{Q}$.

In fact, $\mathbb{Q}(\alpha)$ is precisely the set of all elements of $\mathbb{R}$ of the form $p + q\alpha + r\alpha^2$, where $p, q, r \in \mathbb{Q}$. To show this, we prove that the set of such elements is a subfield. The only (minor) difficulty is finding a multiplicative inverse (see Exercise 4.7).

### 4.2 Rational Expressions

We can perform the operations of addition, subtraction, and multiplication in the polynomial ring $\mathbb{C}[t]$, but (usually) not division. For example, $\mathbb{C}[t]$ does not contain an inverse $t^{-1}$ for $t$ (see Exercise 4.8).

However, we can enlarge $\mathbb{C}[t]$ to provide inverses in a natural way. We have seen that we can think of polynomials $f(t) \in \mathbb{C}[t]$ as functions from $\mathbb{C}$ to itself. Similarly, we can think of fractions $p(t)/q(t) \in \mathbb{C}(t)$ as functions. These are called *rational functions* of the complex variable $t$, and their formal statements in terms of polynomials are *rational expressions* in the indeterminate $t$. However, there is now a technical difficulty. The domain of such a function is not the whole of $\mathbb{C}$; all of the zeros of $q(t)$ have to be removed, or else we are trying to divide by zero. Complex analysts often work in the Riemann sphere $\mathbb{C} \cup \{\infty\}$, and cheerfully let $1/\infty = 0$, but care must be exercised if this is done. The civilised way to proceed is to remove all the potential troublemakers. So we take the domain of $p(t)/q(t)$ to be

$$\{ z \in \mathbb{C} : q(z) \neq 0 \}$$

As we have seen, any complex polynomial $q$ has only finitely many zeros, so the domain here is almost all of $\mathbb{C}$. We have to be careful, but we shouldn’t get into much trouble provided we are attentive.

In the same manner we can also construct the set

$$\mathbb{C}(t_1, \ldots, t_n)$$

of all rational functions in $n$ variables (rational expressions in $n$ indeterminates). One use of such functions is to specify the subfield generated by a given set $X$. It is straightforward to prove that $\mathbb{C}(X)$ consists of all rational expressions

$$\frac{p(x_1, \ldots, x_n)}{q(y_1, \ldots, y_n)}$$

where $p, q$ are polynomials over $\mathbb{Q}$, the $x_j$ and $y_j$ belong to $X$, and $q(x_1, \ldots, x_n) \neq 0$.

For a proof, see Exercise 4.9.
4.3 Simple Extensions

The basic building-blocks for field extensions are those obtained by adjoining one element.

**Definition 4.10** A simple extension is a field extension \( L : K \) such that \( L = K(\alpha) \) for some \( \alpha \in L \).

**Examples 4.11**

1. As the notation shows, the extensions in Examples 4.9 are all simple.

2. **Beware:** An extension may be simple without appearing to be. Consider \( L = \mathbb{Q}(i, -i, \sqrt{5}, -\sqrt{5}) \). As written, it appears to require the adjunction of four new elements. Clearly, just two, \( i \) and \( \sqrt{5} \), suffice. But we claim that in fact only one element is needed, because \( L = L' \) where \( L' = \mathbb{Q}(i + \sqrt{5}) \), which is obviously simple. To prove this, it is enough to show that \( i \in L' \) and \( \sqrt{5} \in L' \), because these imply that \( L \subseteq L' \) and \( L' \subseteq L \), so \( L = L' \). Now \( L' \) contains

\[
(i + \sqrt{5})^2 = -1 + 2i\sqrt{5} + 5 = 4 + 2i\sqrt{5}
\]

Thus, it also contains

\[
(i + \sqrt{5})(4 + 2i\sqrt{5}) = 14i - 2\sqrt{5}
\]

Therefore, it contains

\[
14i - 2\sqrt{5} + 2(i + \sqrt{5}) = 16i
\]

so it contains \( i \). But then it also contains \( (i + \sqrt{5}) - i = \sqrt{5} \). Therefore, \( L = L' \) as claimed, and the extension \( \mathbb{Q}(i, -i, \sqrt{5}, -\sqrt{5}) : \mathbb{Q} \) is in fact simple.

3. On the other hand, \( \mathbb{R} : \mathbb{Q} \) is not a simple extension (Exercise 4.5).

Our aim in the next chapter is to classify all possible simple extensions. We end this chapter by formulating the concept of isomorphism of extensions. In Chapter 5 we develop techniques for constructing all possible simple extensions up to isomorphism.

**Definition 4.12** An isomorphism between two field extensions \( \iota : K \rightarrow \hat{K} \), \( j : L \rightarrow \hat{L} \) is a pair \((\lambda, \mu)\) of field isomorphisms \( \lambda : K \rightarrow L \), \( \mu : \hat{K} \rightarrow \hat{L} \), such that for all \( k \in K \)

\[
j(\lambda(k)) = \mu(\iota(k))
\]
Another, more pictorial way of putting this is to say that the diagram

\[
K \xrightarrow{\lambda} \hat{K} \\
\lambda \downarrow \downarrow \mu \\
L \xrightarrow{j} \hat{L}
\]

commutes — that is, the two paths from \( K \) to \( \hat{L} \) give the same map.

The reason for setting up the definition like this is that in addition to the field structure being preserved by isomorphism, the embedding of the small field in the large one is also preserved.

Various identifications may be made. If we identify \( K \) and \( \iota(K) \), and \( L \) and \( j(L) \), then \( \iota \) and \( j \) are inclusions, and the commutativity condition now becomes

\[\mu|_K = \lambda\]

where \( \mu|_K \) denotes the restriction of \( \mu \) to \( K \). If we further identify \( K \) and \( L \) then \( \lambda \) becomes the identity, and so \( \mu|_K \) is the identity. In what follows we shall attempt to use these identified conditions wherever possible. But on a few occasions (notably Theorem 9.6) we shall need the full generality of the first definition.

---

**Exercises**

4.1 Prove that isomorphism of field extensions is an equivalence relation.

4.2 Find the subfields of \( \mathbb{C} \) generated by:

a. \( \{0, 1\} \)

b. \( \{0\} \)

c. \( \{0, 1, i\} \)

d. \( \{i, \sqrt{2}\} \)

e. \( \{\sqrt{2}, \sqrt{3}\} \)

f. \( \mathbb{R} \)

g. \( \mathbb{R} \cup \{i\} \)

4.3 Describe the subfields of \( \mathbb{C} \) of the form:

a. \( \mathbb{Q}(\sqrt{2}) \)

b. \( \mathbb{Q}(i) \)

c. \( \mathbb{Q}(\alpha) \) where \( \alpha \) is the real cube root of 2

d. \( \mathbb{Q}(\sqrt{5}, \sqrt{7}) \)
4.4 This exercise illustrates a technique that we tacitly assume in several subsequent exercises and examples.

Prove that \(1, \sqrt{2}, \sqrt{3}, \sqrt{6}\) are linearly independent over \(\mathbb{Q}\).

(Hint: Suppose that \(p + q\sqrt{2} + r\sqrt{3} + s\sqrt{6} = 0\) with \(p, q, r, s \in \mathbb{Q}\). We may suppose that \(r \neq 0\) or \(s \neq 0\) (why?). If so, then we can write \(\sqrt{3}\) in the form

\[
\sqrt{3} = \frac{a + b\sqrt{2}}{c + d\sqrt{2}} = e + f\sqrt{2}
\]

where \(a, b, c, d, e, f \in \mathbb{Q}\). Square both sides and obtain a contradiction.)

4.5 Show that \(\mathbb{R}\) is not a simple extension of \(\mathbb{Q}\) as follows:

a. \(\mathbb{Q}\) is countable.

b. Any simple extension of a countable field is countable.

c. \(\mathbb{R}\) is not countable.

4.6 Find a formula for the inverse of \(p + qi + r\sqrt{5} + si\sqrt{5}\), where \(p, q, r, s \in \mathbb{Q}\).

4.7 Find a formula for the inverse of \(p + q\alpha + r\alpha^2\), where \(p, q, r \in \mathbb{Q}\) and \(\alpha = \sqrt{3}\).

4.8 Prove that \(t\) has no multiplicative inverse in \(\mathbb{C}[t]\).

4.9 Prove that \(\mathbb{C}(X)\) consists of all rational expressions

\[
\frac{p(x_1, \ldots, x_n)}{q(y_1, \ldots, y_n)}
\]

where \(p, q \in \mathbb{Q}[t]\), the \(x_j\) and \(y_j\) belong to \(X\), and \(q(x_1, \ldots, x_n) \neq 0\).

4.10 Mark the following true or false.

a. If \(X\) is the empty set, then \(\mathbb{Q}(X) = \mathbb{Q}\).

b. If \(X\) is a subset of \(\mathbb{Q}\), then \(\mathbb{Q}(X) = \mathbb{Q}\).

c. If \(X\) contains an irrational number, then \(\mathbb{Q}(X) \neq \mathbb{Q}\).

d. \(\mathbb{Q}(\sqrt{2}) = \mathbb{Q}\).

e. \(\mathbb{Q}(\sqrt{2}) = \mathbb{R}\).

f. \(\mathbb{R}(\sqrt{2}) = \mathbb{R}\).

g. Every subfield of \(\mathbb{C}\) contains \(\mathbb{Q}\).

h. Every subfield of \(\mathbb{C}\) contains \(\mathbb{R}\).

i. If \(\alpha \neq \beta\) and both are irrational, then \(\mathbb{Q}(\alpha, \beta)\) is not a simple extension of \(\mathbb{Q}\).
Chapter 5

Simple Extensions

The basic building block of field theory is the simple field extension. Here one new element \( \alpha \) is adjoined to a given subfield \( K \) of \( \mathbb{C} \), along with all rational expressions in that element over \( K \). Any finitely generated extension can be obtained by a sequence of simple extensions, so the structure of a simple extension provides vital information about all of the extensions that we shall encounter.

We first classify simple extensions into two very different kinds: transcendental and algebraic. If the new element \( \alpha \) satisfies a polynomial equation over \( K \), then the extension is algebraic; if not, it is transcendental. Up to isomorphism, \( K \) has exactly one simple transcendental extension. For most fields \( K \) there are many more possibilities for simple algebraic extensions; they are classified by the irreducible polynomials \( m \) over \( K \).

The structure of simple algebraic extensions can be described in terms of the polynomial ring \( K[\alpha] \), with operations being performed modulo \( m \). In Chapter 16 we generalize this construction using the notion of an ideal.

5.1 Algebraic and Transcendental Extensions

Recall that a simple extension of a subfield \( K \) of \( \mathbb{C} \) takes the form \( K(\alpha) \) where in nontrivial cases \( \alpha \not\in K \). We classify the possible simple extensions for any \( K \). There are two distinct types: algebraic and transcendental.

**Definition 5.1** Let \( K \) be a subfield of \( \mathbb{C} \) and let \( \alpha \in \mathbb{C} \). Then \( \alpha \) is algebraic over \( K \) if there exists a nonzero polynomial \( p \) over \( K \) such that \( p(\alpha) = 0 \). Otherwise, \( \alpha \) is transcendental over \( K \).

We shorten algebraic over \( \mathbb{Q} \) to algebraic, and transcendental over \( \mathbb{Q} \) to transcendental.

**Examples 5.2**

1. The number \( \alpha = \sqrt{2} \) is algebraic because \( \alpha^2 - 2 = 0 \).
2. The number \( \alpha = \sqrt[3]{2} \) is algebraic because \( \alpha^3 - 2 = 0 \).
3. The number $\pi = 3.14159\ldots$ is transcendental. We postpone a proof to Chapter 24. In Chapter 7 we use the transcendence of $\pi$ to prove the impossibility of squaring the circle.

4. The number $\alpha = \sqrt{\pi}$ is algebraic over $\mathbb{Q}(\pi)$ because $\alpha^2 - \pi = 0$.

5. However, $\alpha - \sqrt{\pi}$ is transcendental over $\mathbb{Q}$. To see why, suppose that $p(\sqrt{\pi}) = 0$ where $0 \neq p(t) \in \mathbb{Q}[t]$. Separating out terms of odd and even degree, we can write this as $a(\pi) + b(\pi)\sqrt{\pi} = 0$, so $a(\pi) = -b(\pi)\sqrt{\pi}$ and $a^2(\pi) = \pi b^2(\pi)$. Thus, $f(\pi) = 0$, where

$$f(t) = a^2(t) - tb^2(t) \in \mathbb{Q}[t]$$

Now $\partial(a^2)$ is even, and $\partial(tb^2)$ is odd, so the difference $f(t)$ is nonzero. But this implies that $\pi$ is algebraic, a contradiction.

In the next few sections we classify all possible simple extensions, and find ways to construct them. The transcendental case is very straightforward: if $K(t)$ is the set of rational functions of the indeterminate $t$ over $K$, then $K(t) : K$ is the unique simple transcendental extension of $K$ up to isomorphism. If $K(\alpha) : K$ is algebraic, the possibilities are richer, but tractable. We show that there is a unique monic irreducible polynomial $m$ over $K$ such that $m(\alpha) = 0$, and that $m$ determines the extension uniquely up to isomorphism.

We begin by constructing a simple transcendental extension of any subfield.

**THEOREM 5.3**

The set of rational expressions $K(t)$ is a simple transcendental extension of the subfield $K$ of $\mathbb{C}$.

**PROOF** Clearly, $K(t) : K$ is a simple extension generated by $t$. If $p$ is a polynomial over $K$ such that $p(t) = 0$, then $p = 0$ by definition of $K(t)$, so the extension is transcendental.

5.2 **The Minimal Polynomial**

The construction of simple algebraic extensions is a much more delicate issue. It is controlled by a polynomial associated with the generator $\alpha$ of $K(\alpha) : K$ called the minimal polynomial. To define it we first set up a technical definition.

**DEFINITION 5.4** A polynomial $f(t) = a_0 + a_1 t + \cdots + a_n t^n$ over a subfield $K$ of $\mathbb{C}$ is monic if $a_n = 1$.
Clearly, every polynomial is a constant multiple of some monic polynomial, and for a nonzero polynomial this monic polynomial is unique. Further, the product of two monic polynomials is again monic.

Now suppose that \( K(\alpha) : K \) is a simple algebraic extension. There is a polynomial \( p \) over \( K \) such that \( p(\alpha) = 0 \). We may suppose that \( p \) is monic. Therefore, there exists at least one monic polynomial of smallest degree that has \( \alpha \) as a zero. We claim that \( p \) is unique. To see why, suppose that \( p, q \) are two such. Then \( p(\alpha) - q(\alpha) = 0 \), so if \( p \neq q \) then some constant multiple of \( p - q \) is a monic polynomial with \( \alpha \) as a zero, contrary to the definition. Hence, there is a unique monic polynomial \( p \) of smallest degree such that \( p(\alpha) = 0 \). We give this a name.

**Definition 5.5** Let \( L : K \) be a field extension, and suppose that \( \alpha \in L \) is algebraic over \( K \). Then the minimal polynomial of \( \alpha \) over \( K \) is the unique monic polynomial \( m \) over \( K \) of smallest degree such that \( m(\alpha) = 0 \).

For example, \( i \in \mathbb{C} \) is algebraic over \( \mathbb{R} \). If we let \( m(i) = i^2 + 1 \), then \( m(i) = 0 \). Clearly, \( m \) is monic. The only monic polynomials over \( \mathbb{R} \) of smaller degree are those of the form \( r + i \), where \( r \in \mathbb{R} \), or the constant polynomial 1. But \( i \) cannot be a zero of any of these, or else we would have \( i \in \mathbb{R} \). Hence the minimal polynomial of \( i \) over \( \mathbb{R} \) is \( i^2 + 1 \).

It is natural to ask which polynomials can be minimal. The next lemma provides information on this question.

**Lemma 5.6**
If \( \alpha \) is an algebraic element over the subfield \( K \) of \( \mathbb{C} \), then the minimal polynomial of \( \alpha \) over \( K \) is irreducible over \( K \). It divides every polynomial of which \( \alpha \) is a zero.

**Proof**  Suppose that the minimal polynomial \( m \) of \( \alpha \) over \( K \) is reducible so that \( m = fg \) where \( f \) and \( g \) are of smaller degree. We may assume \( f \) and \( g \) are monic. Since \( m(\alpha) = 0 \) we have \( f(\alpha)g(\alpha) = 0 \), so either \( f(\alpha) = 0 \) or \( g(\alpha) = 0 \). But this contradicts the definition of \( m \). Hence \( m \) is irreducible over \( K \).

Now suppose that \( p \) is a polynomial over \( K \) such that \( p(\alpha) = 0 \). By the division algorithm, there exist polynomials \( q \) and \( r \) over \( K \) such that \( p = mq + r \) and \( \deg r < \deg m \). Then \( 0 = p(\alpha) = 0 + r(\alpha) \). If \( r \neq 0 \) then a suitable constant multiple of \( r \) is monic, which contradicts the definition of \( m \). Therefore, \( r = 0 \), so \( m \) divides \( p \).

Conversely, if \( K \) is a subfield of \( \mathbb{C} \), then it is easy to show that any irreducible polynomial over \( K \) can be the minimum polynomial of an algebraic element over \( K \).

**Theorem 5.7**
If \( K \) is any subfield of \( \mathbb{C} \) and \( m \) is any irreducible monic polynomial over \( K \), then there exists \( \alpha \in \mathbb{C} \), algebraic over \( K \), such that \( \alpha \) has minimal polynomial \( m \) over \( K \).
PROOF Let $\alpha$ be any zero of $m$ in $\mathbb{C}$. Then $m(\alpha) = 0$, so the minimal polynomial $f$ of $\alpha$ over $K$ divides $m$. But $m$ is irreducible over $K$ and both $f$ and $m$ are monic; therefore, $f = m$. \hfill \square

5.3 Simple Algebraic Extensions

Next, we describe the structure of the field extension $K(\alpha): K$ when $\alpha$ has minimal polynomial $m$ over $K$. We proceed by analogy with a basic concept of number theory. Recall from Section 3.5 that for any positive integer $n$ it is possible to perform arithmetic modulo $n$, and that integers $a, b$ are congruent modulo $n$, written

$$a \equiv b \pmod{n}$$

if $a - b$ is divisible by $n$. In the same way, given a polynomial $m \in K[t]$, we can calculate with polynomials modulo $m$. We say that polynomials $a, b \in K[t]$ are congruent modulo $m$, written

$$a \equiv b \pmod{m}$$

if $a(t) - b(t)$ is divisible by $m(t)$ in $K[t]$.

**Lemma 5.8**

Suppose that $a_1 \equiv a_2 \pmod{m}$ and $b_1 \equiv b_2 \pmod{m}$. Then $a_1 + a_2 \equiv b_1 + b_2 \pmod{m}$, and $a_1a_2 \equiv b_1b_2 \pmod{m}$.

**Proof** We know that $a_1 - a_2 = am$ and $b_1 - b_2 = bm$ for polynomials $a, b \in K[t]$. Now

$$(a_1 + a_2) - (b_1 + b_2) = (a_1 - b_1) + (a_2 - b_2) = (a - b)m$$

which proves the first statement. For the product, we need a slightly more elaborate argument:

$$a_1b_1 - a_2b_2 = a_1b_1 - a_1b_2 + a_1b_2 - a_2b_2$$

$$= a_1(b_1 - b_2) + b_2(a_1 - a_2)$$

$$- (a_1b + b_2a)m$$

\hfill \square

**Lemma 5.9**

Every polynomial $a \in K[t]$ is congruent modulo $m$ to a unique polynomial of degree $< \deg m$. 
5.3 Simple Algebraic Extensions

**Proof**  Divide $a$ by $m$ with remainder, so that $a = qm + r$ where $q, r \in K[t]$ and $\partial r < \partial m$. Then $a - r = qm$, so $a \equiv r (\text{mod } m)$. It remains to prove uniqueness. Suppose that $r \equiv s (\text{mod } m)$ where $\partial r, \partial s < \partial m$. Then $r - s$ is divisible by $m$ but has smaller degree than $m$. Therefore, $r - s = 0$, so $r = s$, proving uniqueness.

We call $r$ the reduced form of $a$ modulo $m$. Lemma 5.9 shows that we can calculate with polynomials modulo $m$ in terms of their reduced forms. Indeed, the reduced form of $a + b$ is the reduced form of $a$ plus the reduced form of $b$, while the reduced form of $ab$ is the remainder, after dividing by $m$, of the product of the reduced form of $a$ and the reduced form of $b$.

Slightly more abstractly, we can work with equivalence classes. The relation $\equiv (\text{mod } m)$ is an equivalence relation on $K[t]$, so it partitions $K[t]$ into equivalence classes. We write $[a]$ for the equivalence class of $a \in K[t]$. Clearly,

$$[a] = \{ f \in K[t] : m|(a - f) \}$$

The sum and product of $[a]$ and $[b]$ can be defined as:

$$[a] + [b] = [a + b] \quad [a][b] = [ab]$$

Each equivalence class contains a unique polynomial of degree $< \partial m$, namely, the reduced form of $a$. Therefore, algebraic computations with equivalence classes are the same as computations with reduced forms, and both are the same as computations in $K[t]$ with the added convention that $m(t)$ is identified with $0$. In particular, the classes $[0]$ and $[1]$ are additive and multiplicative identities, respectively.

We write

$$K[t]/\langle m \rangle$$

for the set of equivalence classes of $K[t]$ modulo $m$. Readers who know about ideals in rings will see at once that $K[t]/\langle m \rangle$ is a thin disguise for the quotient ring of $K[t]$ by the ideal generated by $m$, and the equivalence classes are cosets of that ideal, but at this stage of the book these concepts are more abstract than we really need.

A key result is Theorem 5.10.

**Theorem 5.10**

*Every nonzero element of $K[t]/\langle m \rangle$ has a multiplicative inverse in $K[t]/\langle m \rangle$ if and only if $m$ is irreducible in $K[t]$.\]**

**Proof**  If $m$ is reducible, then $m = ab$ where $\partial a, \partial b < \partial m$. Then $[a][b] = [ab] = [m] = [0]$. Suppose that $[a]$ has an inverse $[c]$, so that $[c][a] = [1]$. Then $[0] = [c][0] = [c][a][b] = [1][b] = [b]$, so $m$ divides $b$. Since $\partial b < \partial m$, we must have $b = 0$ so $m = 0$, but by convention $0$ is not irreducible.

If $m$ is irreducible, let $a \in K[t]$ with $[a] \neq [0]$; that is, $m|a$. Therefore, $a$ is prime to $m$, so their highest common factor is 1. By Theorem 3.9, there exist $h, k \in K[t]$
such that \( ha + km = 1 \). Then \([h][a] + [k][m] = [1]\), but \([m] = [0]\) so \([1] = [h][a] + [k][m] = [h][a] + [k][0] = [h][a] + [0] = [h][a]\). Thus, \([h]\) is the required inverse.

Again, in abstract terminology, what we have proved is that \( K[t]/(m) \) is a field if and only if \( m \) is irreducible in \( K[t] \). See Chapter 16 for a full explanation and generalizations.

5.4 Classifying Simple Extensions

We shall now demonstrate that the above methods suffice for the construction of all possible simple extensions (up to isomorphism). Again, transcendental extensions are easily dealt with.

**Theorem 5.11**

Every simple transcendental extension \( K(\alpha) : K \) is isomorphic to the extension \( K(t) : K \) of rational expressions in an indeterminate \( t \) over \( K \). The isomorphism \( K(t) \rightarrow K \) can be chosen to map \( t \) to \( \alpha \), and to be the identity on \( K \).

**Proof** Define a map \( \phi : K(t) \rightarrow K(\alpha) \) by

\[
\phi(f(t)/g(t)) = f(\alpha)/g(\alpha)
\]

If \( g \neq 0 \), then \( g(\alpha) \neq 0 \) (since \( \alpha \) is transcendental) so this definition makes sense. It is clearly a homomorphism, and a simple calculation shows that it is a monomorphism. It is clearly onto, and so is an isomorphism. Further, \( \phi|_K \) is the identity, so that \( \phi \) defines an isomorphism of extensions. Finally, \( \phi(t) = \alpha \).

The classification for simple algebraic extensions is just as straightforward, but more interesting:

**Theorem 5.12**

Let \( K(\alpha) : K \) be a simple algebraic extension, and let the minimal polynomial of \( \alpha \) over \( K \) be \( m \). Then \( K(\alpha) : K \) is isomorphic to \( K[t]/(m) \). The isomorphism \( K[t]/(m) \rightarrow K(\alpha) \) can be chosen to map \( t \) to \( \alpha \) (and to be the identity on \( K \)).

**Proof** The isomorphism is defined by \([p(t)] \mapsto p(\alpha)\), where \([p(t)]\) is the equivalence class of \( p(t) \pmod{m} \). This map is well-defined because \( p(\alpha) = 0 \) if and only if \( m|p \). It is clearly a field monomorphism. It maps \( t \) to \( \alpha \), and its restriction to \( K \) is the identity.
5.4 Classifying Simple Extensions

**COROLLARY 5.13**
Suppose $K(\alpha) : K$ and $K(\beta) : K$ are simple algebraic extensions, such that $\alpha$ and $\beta$ have the same minimal polynomial $m$ over $K$. Then the two extensions are isomorphic, and the isomorphism of the large fields can be taken to map $\alpha$ to $\beta$ (and to be the identity on $K$).

**PROOF** Both extensions are isomorphic to $K[t]/(m)$. The isomorphisms concerned map $t$ to $\alpha$ and $t$ to $\beta$, respectively. Call them $\iota$, $j$, respectively. Then $j\iota^{-1}$ is an isomorphism from $K(\alpha)$ to $K(\beta)$ that is the identity on $K$ and maps $\alpha$ to $\beta$. \[\]

**LEMMA 5.14**
Let $K(\alpha) : K$ be a simple algebraic extension, let the minimal polynomial of $\alpha$ over $K$ be $m$, and let $\delta m = n$. Then $\{1, \alpha, \ldots, \alpha^{n-1}\}$ is a basis for $K(\alpha)$ over $K$. In particular, $[K(\alpha) : K] = n$.

**PROOF** The theorem is a restatement of Lemma 5.9. \[\]

For certain later applications we need a slightly stronger version of Theorem 5.12 to cover extensions of isomorphic (rather than identical) fields. Before we can state the more general theorem we need the following.

**DEFINITION 5.15** Let $\iota : K \to L$ be a field monomorphism. Then there is a map $\hat{\iota} : K[t] \to L[t]$ defined by

$$\hat{\iota}(k_0 + k_1 t + \cdots + k_n t^n) = \iota(k_0) + \iota(k_1)t + \cdots + \iota(k_n)t^n$$

$(k_0, \ldots, k_n \in K)$. It is easy to prove that $\hat{\iota}$ is a monomorphism. If $\iota$ is an isomorphism, then so is $\hat{\iota}$.

The hat is unnecessary, once the statement is clear, and it may be dispensed with. So in the future we use the same symbol $\iota$ for the map between subfields of $\mathbb{C}$ and for its extension to polynomial rings. This will not cause confusion since $\hat{\iota}(k) = \iota(k)$ for any $k \in K$.

**THEOREM 5.16**
Suppose that $K$ and $L$ are subfields of $\mathbb{C}$ and $\iota : K \to L$ is an isomorphism. Let $K(\alpha), L(\beta)$ be simple algebraic extensions of $K$ and $L$, respectively, such that $\alpha$ has minimal polynomial $m_\alpha(t)$ over $K$ and $\beta$ has minimal polynomial $m_\beta(t)$ over $L$. Suppose further that $m_\beta(t) = \iota(m_\alpha(t))$. Then there exists an isomorphism $j : K(\alpha) \to L(\beta)$ such that $j|_K = \iota$ and $j(\alpha) = \beta$. \[\]}
PROOF We can summarize the hypotheses in the diagram

\[ K \rightarrow K(\alpha) \]
\[ \iota \downarrow \quad \downarrow j \]
\[ L \rightarrow L(\beta) \]

where \( j \) is yet to be determined. Using the reduced form, every element of \( K(\alpha) \) is of the form \( p(\alpha) \) for a polynomial \( p \) over \( K \) of degree \( < \delta m_\alpha \). Define \( j(p(\alpha)) = (\iota(p))(\beta) \) where \( \iota(p) \) is defined as above. Everything else follows easily from Theorem 5.12.

The point of this theorem is that the given map \( \iota \) can be extended to a map \( j \) between the larger fields. Such extension theorems, saying that under suitable conditions maps between subobjects can be extended to maps between objects, constitute important weapons in the mathematician's armoury. Using them we can extend our knowledge from small structures to large ones in a sequence of simple steps.

Theorem 5.16 implies that under the given hypotheses the extensions \( K(\alpha) : K \) and \( L(\beta) : L \) are isomorphic. This allows us to identify \( K \) with \( L \) and \( K(\alpha) \) with \( L(\beta) \), via the maps \( \iota \) and \( j \).

Theorems 5.7 and 5.12 together give a complete characterization of simple algebraic extensions in terms of polynomials. Each extension corresponds to an irreducible monic polynomial, and given the small field and this polynomial, we can reconstruct the extension.

Exercises

5.1 Is the extension \( \mathbb{Q}(\sqrt{3}, \sqrt{7}) \) simple? If so, why? If not, why not?

5.2 Find the minimal polynomials over the small field of the following elements in the following extensions:

- a. \( i \) in \( \mathbb{C} : \mathbb{Q} \)
- b. \( i \) in \( \mathbb{C} : \mathbb{R} \)
- c. \( \sqrt{2} \) in \( \mathbb{R} : \mathbb{Q} \)
- d. \( (\sqrt{5} + 1)/2 \) in \( \mathbb{C} : \mathbb{Q} \)
- e. \( (i\sqrt{3} - 1)/2 \) in \( \mathbb{C} : \mathbb{Q} \)

5.3 Show that if \( \alpha \) has minimal polynomial \( t^2 - 2 \) over \( \mathbb{Q} \) and \( \beta \) has minimal polynomial \( t^2 - 4t + 2 \) over \( \mathbb{Q} \), then the extensions \( \mathbb{Q}(\alpha) : \mathbb{Q} \) and \( \mathbb{Q}(\beta) : \mathbb{Q} \) are isomorphic.

5.4 For which of the following \( m(t) \) and \( K \) do there exist extensions \( K(\alpha) \) of \( K \) for which \( \alpha \) has minimal polynomial \( m(t) \)?
Exercises

a. \( m(t) = t^2 - 4, K = \mathbb{R} \)

b. \( m(t) = t^2 - 3, K = \mathbb{R} \)

c. \( m(t) = t^2 - 3, K = \mathbb{Q} \)

d. \( m(t) = t^7 - 3t^6 + 4t^3 - t - 1, K = \mathbb{R} \)

5.5 Let \( K \) be any subfield of \( \mathbb{C} \) and let \( m(t) \) be a quadratic polynomial over \( K \) (\( \delta m = 2 \)). Show that all zeros of \( m(t) \) lie in an extension \( K(\alpha) \) of \( K \) where \( \alpha^2 = k \in K \). Thus, allowing square roots \( \sqrt{k} \) enables us to solve all quadratic equations over \( K \).

5.6 Construct extensions \( \mathbb{Q}(\alpha) : \mathbb{Q} \) where \( \alpha \) has the following minimal polynomial over \( \mathbb{Q} \):

a. \( t^2 - 5 \)

b. \( t^4 + t^3 + t^2 + t + 1 \)

c. \( t^3 + 2 \)

5.7 Is \( \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5}) : \mathbb{Q} \) a simple extension?

5.8 Suppose that \( m(t) \) is irreducible over \( K \), and \( \alpha \) has minimal polynomial \( m(t) \) over \( K \). Does \( m(t) \) necessarily factorize over \( K(\alpha) \) into linear (degree 1) polynomials? (Hint: Try \( K = \mathbb{Q}, \alpha = \) the real cube root of 2.)

5.9 Mark the following true or false.

a. Every field has nontrivial extensions.

b. Every field has nontrivial algebraic extensions.

c. Every simple extension is algebraic.

d. Every extension is simple.

e. All simple algebraic extensions of a given subfield of \( \mathbb{C} \) are isomorphic.

f. All simple transcendental extensions of a given subfield of \( \mathbb{C} \) are isomorphic.

g. Every minimal polynomial is monic.

h. Monic polynomials are always irreducible.

i. Every polynomial is a constant multiple of an irreducible polynomial.
Chapter 6

The Degree of an Extension

A technique that has become very useful in mathematics is associating a given structure with a different one of a type better understood. In this chapter we exploit the technique by associating a vector space with any field extension. This places at our disposal the machinery of linear algebra — a very successful algebraic theory — and with its aid we can make considerable progress. The machinery is sufficiently powerful to solve three notorious problems which remained unanswered for over 2000 years. We discuss these problems in the next chapter, and devote the present chapter to developing the theory.

6.1 Definition of the Degree

It is not hard to define a vector space structure on a field extension. It already has one! More precisely:

**Theorem 6.1**

If $L : K$ is a field extension, then the operations

$$
(\lambda, u) \mapsto \lambda u \quad (\lambda \in K, u \in L)
$$

$$
(u, v) \mapsto u + v \quad (u, v \in L)
$$

define on $L$ the structure of a vector space over $K$.

**Proof** The set $L$ is a vector space over $K$ if the two operations just defined satisfy the following axioms:

1. $u + v = v + u$ for all $u, v \in L$.

2. $(u + v) + w = u + (v + w)$ for all $u, v, w \in L$.

3. There exists $0 \in L$ such that $0 + u = u$ for all $u \in L$.

4. For any $u \in L$ there exists $-u \in L$ such that $u + (-u) = 0$.

5. If $\lambda \in K, u, v \in L$, then $\lambda(u + v) = \lambda u + \lambda v$. 

6. If 1 is the multiplicative identity of $K$, then $1u = u$ for all $u \in L$.

7. If $\lambda, \mu \in K$, then $\lambda(\mu u) = (\lambda \mu)u$ for all $u \in L$.

Each of these statements follows immediately because $K$ and $L$ are subfields of $\mathbb{C}$ and $K \subseteq L$.

We know that a vector space $V$ over a subfield $K$ of $\mathbb{C}$ (indeed over any field, but we’re not supposed to know about those yet) is uniquely determined, up to isomorphism, by its dimension. The dimension is the number of elements in a basis, a subset of vectors that spans $V$ and is linearly independent over $K$. The following definition is the traditional terminology in the context of field extensions.

**Definition 6.2** The degree $[L : K]$ of a field extension $L : K$ is the dimension of $L$ considered as a vector space over $K$.

**Example 6.3**

1. The complex numbers $\mathbb{C}$ are two-dimensional over the real numbers $\mathbb{R}$, because a basis is $\{1, i\}$. Hence $[\mathbb{C} : \mathbb{R}] = 2$.

2. The extension $\mathbb{Q}(i, \sqrt{5}) : \mathbb{Q}$ has degree 4. The elements $\{1, \sqrt{5}, i, i\sqrt{5}\}$ form a basis for $\mathbb{Q}(i, \sqrt{5})$ over $\mathbb{Q}$, by Example 4.8.

Isomorphic field extensions obviously have the same degree.

---

### 6.2 The Tower Law

The next theorem, known as the (short) tower law, lets us calculate the degree of a complicated extension if we know the degrees of certain simpler ones.

**Theorem 6.4 (Short Tower Law)**

If $K$, $L$, $M$ are subfields of $\mathbb{C}$ and $K \subseteq L \subseteq M$, then

$$[M : K] = [M : L][L : K]$$

**Note:** For those who are happy with infinite cardinals this formula needs no extra explanation; the product on the right is just multiplication of cardinals. For those who are not, the formula needs interpretation if any of the degrees involved is infinite. This interpretation is the obvious one: if either $[M : L]$ or $[L : K] = \infty$, then $[M : K] = \infty$; and if $[M : K] = \infty$, then either $[M : L] = \infty$ or $[L : K] = \infty$. 
6.2 The Tower Law

PROOF  Let \((x_i)_{i \in I}\) be a basis for \(L\) as vector space over \(K\) and let \((y_j)_{j \in J}\) be a basis for \(M\) over \(L\). For all \(i \in I\) and \(j \in J\) we have \(x_i \in L\), \(y_j \in M\). We shall show that \((x_iy_j)_{i \in I, \ j \in J}\) is a basis for \(M\) over \(K\) (where \(x_iy_j\) is the product in the subfield \(M\)). Since dimensions are cardinalities of bases, the theorem will follow.

First, we prove linear independence. Suppose that some finite linear combination of the putative basis elements is zero; that is,

\[
\sum_{i,j} k_{ij} x_i y_j = 0 \quad (k_{ij} \in K)
\]

We can rearrange this as

\[
\sum_j \left( \sum_i k_{ij} x_i \right) y_j = 0
\]

Since the coefficients \(\sum_i k_{ij} x_i\) lie in \(L\) and the \(y_j\) are linearly independent over \(L\),

\[
\sum_i k_{ij} x_i = 0
\]

Repeating the argument inside \(L\) we find that \(k_{ij} = 0\) for all \(i \in I, \ j \in J\). So the elements \(x_iy_j\) are linearly independent over \(K\).

Finally, we show that the \(x_iy_j\) span \(M\) over \(K\). Any element \(x \in M\) can be written

\[
x = \sum_j \lambda_j y_j
\]

for suitable \(\lambda_j \in L\), because the \(y_j\) span \(M\) over \(L\). Similarly, for any \(j \in J\)

\[
\lambda_j = \sum_i \lambda_{ij} x_i
\]

for \(\lambda_{ij} \in K\). Putting the pieces together,

\[
x = \sum_{i,j} \lambda_{ij} x_i y_j
\]

as required. \(\square\)

Example 6.5

Suppose we wish to find \([\mathbb{Q}(\sqrt{2}, \sqrt{3}) : \mathbb{Q}]\). It is easy to see that \(\{1, \sqrt{2}\}\) is a basis for \(\mathbb{Q}(\sqrt{2})\) over \(\mathbb{Q}\). To see this, let \(\alpha \in \mathbb{Q}(\sqrt{2})\). Then \(\alpha = p + q\sqrt{2}\) where \(p, q \in \mathbb{Q}\), proving that \(\{1, \sqrt{2}\}\) spans \(\mathbb{Q}(\sqrt{2})\) over \(\mathbb{Q}\). It remains to show that 1 and \(\sqrt{2}\) are linearly independent over \(\mathbb{Q}\). Suppose that \(p + q\sqrt{2} = 0\), where \(p, q \in \mathbb{Q}\). If \(q \neq 0\), then \(\sqrt{2} = p/q\), which is impossible since \(\sqrt{2}\) is irrational. Therefore, \(q = 0\). But this implies \(p = 0\).
In much the same way we can show that \( \{1, \sqrt{3}\} \) is a basis for \( \mathbb{Q}(\sqrt{2}, \sqrt{3}) \) over \( \mathbb{Q}(\sqrt{2}) \). Every element of \( \mathbb{Q}(\sqrt{2}, \sqrt{3}) \) can be written as \( p + q\sqrt{2} + r\sqrt{3} + s\sqrt{6} \) where \( p, q, r, s \in \mathbb{Q} \). Rewriting this as

\[
(p + q\sqrt{2}) + (r + s\sqrt{3})\sqrt{3}
\]

we see that \( \{1, \sqrt{3}\} \) spans \( \mathbb{Q}(\sqrt{2}, \sqrt{3}) \) over \( \mathbb{Q}(\sqrt{2}) \). To prove linear independence we argue much as above. If

\[
(p + q\sqrt{2}) + (r + s\sqrt{3})\sqrt{3} = 0
\]

then either \( (r + s\sqrt{2}) = 0 \), whence also \( (p + q\sqrt{2}) = 0 \), or else

\[
\sqrt{3} = (p + q\sqrt{2})/(r + s\sqrt{2}) \in \mathbb{Q}(\sqrt{2})
\]

Therefore, \( \sqrt{3} = a + b\sqrt{2} \) where \( a, b \in \mathbb{Q} \). Squaring, we find that \( ab\sqrt{2} \) is rational, which is possible only if either \( a = 0 \) or \( b = 0 \). But then \( \sqrt{3} = a \) or \( \sqrt{3} = b\sqrt{2} \), both of which are absurd unless \( a = b = 0 \). Then \( (p + q\sqrt{2}) = (r + s\sqrt{2}) = 0 \) and we have proved that \( \{1, \sqrt{3}\} \) is a basis. Hence,

\[
[\mathbb{Q}(\sqrt{2}, \sqrt{3}) : \mathbb{Q}] = [\mathbb{Q}(\sqrt{2}, \sqrt{3}) : \mathbb{Q}(\sqrt{2})][\mathbb{Q}(\sqrt{2}) : \mathbb{Q}]
\]

\[
= 2 \times 2 = 4
\]

The theorem even furnishes a basis for \( \mathbb{Q}(\sqrt{2}, \sqrt{3}) \) over \( \mathbb{Q} \): form all possible pairs of products from the two bases \( \{1, \sqrt{2}\} \) and \( \{1, \sqrt{3}\} \) to get the combined basis \( \{1, \sqrt{2}, \sqrt{3}, \sqrt{6}\} \).

By induction on \( n \) we easily parlay the short tower law into a useful generalization:

**COROLLARY 6.6 (Tower Law)**

If \( K_0 \subseteq K_1 \subseteq \cdots \subseteq K_n \) are subfields of \( \mathbb{C} \), then

\[
[K_n : K_0] = [K_n : K_{n-1}][K_{n-1} : K_{n-2}]\cdots[K_1 : K_0]
\]

In order to use the tower law we have to get started. The degree of a simple extension is fairly easy to find.

**PROPOSITION 6.7**

Let \( K(\alpha) : K \) be a simple extension. If it is transcendental, then \( [K(\alpha) : K] = \infty \).

If it is algebraic, then \( [K(\alpha) : K] = \deg m \), where \( m \) is the minimal polynomial of \( \alpha \) over \( K \).

**PROOF** For the transcendental case it suffices to note that the elements \( 1, \alpha, \alpha^2, \ldots \) are linearly independent over \( K \). For the algebraic case, we appeal to Lemma 5.14. \( \square \)
6.2 The Tower Law

For example, we know that \( C = \mathbb{R}(i) \) where \( i \) has minimal polynomial \( t^2 + 1 \), of degree 2, hence \([C : \mathbb{R}] = 2\), which agrees with our previous remarks.

**Example 6.8**

We now illustrate a technique that we shall use, without explicit reference, whenever we discuss extensions of the form \( \mathbb{Q}(\sqrt{\alpha_1}, \ldots, \sqrt{\alpha_n}) : \mathbb{Q} \) with rational \( \alpha_j \). The technique can be used to prove a general theorem about such extensions (see Exercise 6.15). The question we tackle is: find \([\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5}) : \mathbb{Q}]\).

By the tower law,

\[
[\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5}) : \mathbb{Q}] = [\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5}) : \mathbb{Q}(\sqrt{2}, \sqrt{3})][\mathbb{Q}(\sqrt{2}, \sqrt{3}) : \mathbb{Q}(\sqrt{2})][\mathbb{Q}(\sqrt{2}) : \mathbb{Q}]
\]

It is obvious that each factor equals 2, but it takes some effort to prove it. As a cautionary remark, the degree \([\mathbb{Q}(\sqrt{6}, \sqrt{10}, \sqrt{15}) : \mathbb{Q}]\) is 4, not 8 (see Exercise 6.14).

(a) Certainly \([\mathbb{Q}(\sqrt{2}) : \mathbb{Q}] = 2\).

(b) If \( \sqrt{3} \notin \mathbb{Q}(\sqrt{2}) \), then \([\mathbb{Q}(\sqrt{2}, \sqrt{3}) : \mathbb{Q}(\sqrt{2})] = 2\). So suppose \( \sqrt{3} \in \mathbb{Q}(\sqrt{2}) \), implying that

\[ \sqrt{3} = p + q\sqrt{2} \quad p, q \in \mathbb{Q} \]

We argue as in Example 6.5. Squaring,

\[ 3 = (p^2 + 2q^2) + 2pq\sqrt{2} \]

so

\[ p^2 + 2q^2 = 3 \quad pq = 0 \]

If \( p = 0 \), then \( 2q^2 = 3 \), which is impossible by Exercise 1.3. If \( q = 0 \), then \( p^2 = 3 \), which is impossible for the same reason. Therefore, \( \sqrt{3} \notin \mathbb{Q}(\sqrt{2}) \), and \([\mathbb{Q}(\sqrt{2}, \sqrt{3}) : \mathbb{Q}(\sqrt{2})] = 2\).

(c) Finally, we claim that \( \sqrt{5} \notin \mathbb{Q}(\sqrt{2}, \sqrt{3}) \). Here we need a new idea. Suppose

\[ \sqrt{5} = p + q\sqrt{2} + r\sqrt{3} + s\sqrt{6} \quad p, q, r, s \in \mathbb{Q} \]

Squaring:

\[ 5 = p^2 + 2q^2 + 3r^2 + 6s^2 + (2pq + 6rs)\sqrt{2} + (2pr + 4qs)\sqrt{3} + (2ps + 2qr)\sqrt{6} \]

whence

\[
p^2 + 2q^2 + 3r^2 + 6s^2 = 5
\]

\[ pq + 3rs = 0 \]

\[ pr + 2qs = 0 \]

\[ ps + qr = 0 \]

(6.1)
The new idea is to observe that if \((p, q, r, s)\) satisfies (6.1), then so do \((p, q, -r, -s)\), \((p, -q, r, -s)\), and \((p, -q, -r, s)\). Therefore,

\[
\begin{align*}
p + q\sqrt{2} + r\sqrt{3} + s\sqrt{6} &= \sqrt{5} \\
p + q\sqrt{2} - r\sqrt{3} - s\sqrt{6} &= \pm\sqrt{5} \\
p - q\sqrt{2} + r\sqrt{3} - s\sqrt{6} &= \pm\sqrt{5} \\
p - q\sqrt{2} - r\sqrt{3} + s\sqrt{6} &= \pm\sqrt{5}
\end{align*}
\]

Adding the first two equations, we get \(p + q\sqrt{2} = 0\) or \(p + q\sqrt{2} = \sqrt{5}\), each of which implies that \(p = q = 0\). Adding the first and third, \(r\sqrt{3} = 0\) or \(r\sqrt{3} = \sqrt{5}\), so \(r = 0\). Finally, \(s = 0\) since \(s\sqrt{6} = \sqrt{5}\) is impossible by Exercise 1.3.

Having proved the claim, we immediately deduce that

\[
[\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5}) : \mathbb{Q}(\sqrt{2}, \sqrt{3})] = 2
\]

which implies that \([\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5}) : \mathbb{Q}] = 8\).

Linear algebra is at its most powerful when dealing with finite-dimensional vector spaces. Accordingly we concentrate on field extensions that give rise to such vector spaces.

**Definition 6.9**

A finite extension is one whose degree is finite.

Proposition 6.7 implies that any simple algebraic extension is finite. The converse is not true, but certain partial results are (see Exercise 6.16). In order to state what is true we need:

**Definition 6.10**

An extension \(L : K\) is algebraic if every element of \(L\) is algebraic over \(K\).

Algebraic extensions need not be finite (see Exercise 6.12), but every finite extension is algebraic. More generally:

**Lemma 6.11**

\(L : K\) is a finite extension if and only if \(L\) is algebraic over \(K\) and there exist finitely many elements \(\alpha_1, \ldots, \alpha_s \in L\) such that \(L = K(\alpha_1, \ldots, \alpha_s)\).

**Proof** Induction using Theorem 6.4 and Proposition 6.7 shows that any algebraic extension \(K(\alpha_1, \ldots, \alpha_s) : K\) is finite. Conversely, let \(L : K\) be a finite extension. Then there is a basis \(\{\alpha_1, \ldots, \alpha_s\}\) for \(L\) over \(K\), whence \(L = K(\alpha_1, \ldots, \alpha_s)\). It remains to show that \(L : K\) is algebraic. Let \(r\) be any element of \(L\) and let \(n = [L : K]\)
The set \( \{1, x, \ldots, x^n\} \) contains \( n + 1 \) elements, which must therefore be linearly dependent over \( K \). Hence
\[
k_0 + k_1 x + \cdots + k_n x^n = 0
\]
for \( k_0, \ldots, k_n \in K \), and \( x \) is algebraic over \( K \). \( \square \)

---

**Exercises**

6.1 Find the degrees of the following extensions:

a. \( \mathbb{C} : \mathbb{Q} \)

b. \( \mathbb{R}(\sqrt{5}) : \mathbb{R} \)

c. \( \mathbb{Q}(\alpha) : \mathbb{Q} \) where \( \alpha \) is the real cube root of 2

d. \( \mathbb{Q}(3, \sqrt{5}, \sqrt{11}) : \mathbb{Q} \)

e. \( \mathbb{Q}(\sqrt{6}) : \mathbb{Q} \)

f. \( \mathbb{Q}(\alpha) : \mathbb{Q} \) where \( \alpha^7 = 3 \)

6.2 Show that every element of \( \mathbb{Q}(\sqrt{5}, \sqrt{7}) \) can be expressed uniquely in the form
\[
p + q\sqrt{5} + r\sqrt{7} + s\sqrt{35}
\]
where \( p, q, r, s \in \mathbb{Q} \). Calculate explicitly the inverse of such an element.

6.3 If \( [L : K] \) is a prime number, show that the only fields \( M \) such that \( K \subseteq M \subseteq L \) are \( K \) and \( L \) themselves.

6.4 If \( [L : K] = 1 \), show that \( K = L \).

6.5 Write out in detail the inductive proof of Corollary 6.6.

6.6 Prove that \( [L : K] \) is finite if and only if \( L = K(\alpha, \ldots, \alpha_r) \) where \( r \) is finite and each \( \alpha_i \) is algebraic over \( K \).

6.7 Let \( L : K \) be an extension. Show that multiplication by a fixed element of \( L \) is a linear transformation of \( L \) considered as a vector space over \( K \). When is this linear transformation nonsingular?

6.8 Let \( L : K \) be a finite extension, and let \( p \) be an irreducible polynomial over \( K \). Show that if \( \partial p \) and \( [L : K] \) are coprime, then \( p \) has no zeros in \( L \).

6.9 If \( L : K \) is algebraic and \( M : L \) is algebraic, is \( M : K \) algebraic? Note that you may not assume the extensions are finite.

6.10 Prove that \( \mathbb{Q}(\sqrt{3}, \sqrt{5}) = \mathbb{Q}(\sqrt{3} + \sqrt{5}) \). Try to generalize your result.
6.11* Prove that the square roots of all prime numbers are linearly independent over \( \mathbb{Q} \). Deduce that algebraic extensions need not be finite.

6.12 Find a basis for \( \mathbb{Q}(\sqrt{1 + \sqrt{3}}) \) over \( \mathbb{Q} \) and hence find the degree of \( \mathbb{Q}(\sqrt{1 + \sqrt{3}}) : \mathbb{Q} \). (Hint: You will need to prove that \( 1 + \sqrt{3} \) is not a square in \( \mathbb{Q}(\sqrt{3}) \).

6.13 If \( [L : K] \) is prime, show that \( L \) is a simple extension of \( K \).

6.14 Show that \( [\mathbb{Q}(\sqrt{6}, \sqrt{10}, \sqrt{15}) : \mathbb{Q}] = 4 \), not 8.

6.15* Let \( K \) be a subfield of \( \mathbb{C} \) and let \( a_1, \ldots, a_n \) be elements of \( K \) such that any product \( a_{j_1} \cdots a_{j_k} \), with distinct indices \( j_i \), is not a square in \( K \). Let \( \alpha_j = \sqrt{a_j} \) for \( 1 \leq j \leq n \). Prove that \( \left[ K(\alpha_1, \ldots, \alpha_n) : K \right] = 2^n \).

If \( K = \mathbb{Q} \), how can we verify the hypotheses on the \( a_j \) by looking at their prime factorizations?

6.16* Let \( L : K \) be an algebraic extension and suppose that \( K \) is an infinite field. Prove that \( L : K \) is simple if and only if there are only finitely many fields \( M \) such that \( K \subseteq M \subseteq L \), as follows.

a. Assume only finitely many \( M \) exist. Use Lemma 6.11 to show that \( L : K \) is finite.

b. Assume \( L = K(\alpha_1, \alpha_2) \). For each \( \beta \in K \) let \( J_\beta = K(\alpha_1 + \beta \alpha_2) \). Only finitely many distinct \( J_\beta \) can occur; hence show that \( L = J_\beta \) for some \( \beta \).

c. Use induction to prove the general case.

d. For the converse, let \( L = K(\alpha) \) be simple algebraic, with \( K \subseteq M \subseteq L \).

Let \( m \) be the minimal polynomial of \( \alpha \) over \( K \), and let \( m_M \) be the minimal polynomial of \( \alpha \) over \( M \). Show that \( m_M | m \) in \( L[t] \). Prove that \( m_M \) determines \( M \) uniquely, and that only finitely many \( m_M \) can occur.

6.17 Mark the following true or false.

a. Extensions of the same degree are isomorphic.

b. Isomorphic extensions have the same degree.

c. Every algebraic extension is finite.

d. Every transcendental extension is not finite.

e. Every element of \( \mathbb{C} \) is algebraic over \( \mathbb{R} \).

f. Every extension of \( \mathbb{R} \) is finite.

g. Every algebraic extension of \( \mathbb{Q} \) is finite.

h. Every vector space is isomorphic to the vector space corresponding to some field extension.

i. Every extension of a finite field is finite.
Chapter 7

Ruler-and-Compass Constructions

Already, we are in a position to see some payoff from our efforts. The degree of a field extension is a surprisingly powerful tool. Even before we get into Galois theory proper, we can apply the degree to a warm-up problem — indeed, several. The problems come from classical Greek geometry, and we will do something much more interesting and difficult than solving them. We will prove that no solutions exist.

According to Plato the only perfect geometrical figures are the straight line and the circle. In the most widely known parts of ancient Greek geometry, this belief had the effect of restricting the (conceptual) instruments available for performing geometrical constructions to two: the ruler and the compasses. (It’s like scissors — one gadget for drawing circles is a pair of compasses. A compass is a magnetic needle that points north.) The ruler, furthermore, was a single unmarked straight edge.

With these instruments alone it is possible to perform a wide range of constructions, as Euclid systematically set out in his Elements somewhere around 300 BC. Line segments can be divided into arbitrarily many equal parts, angles can be bisected, parallel lines can be drawn. Given any polygon, it is possible to construct a square of equal area, or twice the area. And so on. However, there are many geometric problems that clearly should have solutions, but for which the tools of ruler and compasses are inadequate. There are three famous constructions that the Greeks could not perform using these tools: duplicating the cube, trisecting the angle, and squaring the circle. These ask, respectively, for a cube twice the volume of a given cube, an angle one third the size of a given angle, and a square of area equal to a given circle.

It is not surprising that the Greeks found these constructions so difficult; they are impossible. But the Greeks had neither the methods to prove the impossibility nor, it appears, any clear suspicion that solutions did not exist. However, they were well aware that by going outside the Platonic constraints, these problems can be solved. Archimedes and others knew that angles can be trisected using a marked ruler, as in Figure 7.1. The ruler has marked on it two points distance $r$ apart. Given $\angle AOB = \theta$ draw a circle centre O with radius $r$, cutting OA at X, OB at Y. Place the ruler with its edge through X and one mark on the line OY at D, slide it until the other marked point lies on the circle at E. Then $\angle EDO = \theta/3$. For a proof, see Exercise 7.3.

Setting your compasses up against the ruler so that the pivot point and the pencil effectively constitute such marks also provides a trisection, but again goes beyond what we mean by ruler-and-compass construction. (To be pedantic, a ruler-and-compasses construction, but pedantry has to stop somewhere.) Many other uses of exotic instruments are catalogued in Dudley (1987), which examines the history of
trisection attempts. Euclid may have limited himself to an unmarked ruler (plus compasses) because it made his axiomatic treatment more convincing. It is not entirely clear what axioms should apply to a marked ruler — the distance between the marks causes difficulties.

The Greeks solved all three problems using conic sections or more recondite curves such as the conchoid of Nichomedes or the quadratrix (Klein et al., 1962; Coolidge, 1963). Archimedes, tackling the problem of squaring the circle in a characteristically ingenious manner, proved a result which would now be written

$$\frac{3}{71} \frac{10}{7} < \pi < \frac{1}{7}$$

This was a remarkable achievement with the limited techniques available, and refinements of his method can approximate $\pi$ to any required degree of precision.

Such extensions of the apparatus solve the practical problem, but it is the theoretical one that holds the most interest. What, precisely, are the limitations on ruler-and-compass constructions? With the machinery now at our disposal it is relatively simple to characterize these limitations, and thereby give a complete answer to all three problems. We use coordinate geometry to express problems in algebraic terms, and apply the theory of field extensions to the algebraic questions that arise.

7.1 Algebraic Formulation

The first step is to formalize the intuitive idea of a ruler-and-compass construction. Assume that a set $P_0$ of points in the Euclidean plane $\mathbb{R}^2$ is given, and consider operations of the following two kinds:

* **Ruler** Through any two points of $P_0$ draw a straight line.

* **Compasses** Draw a circle, whose centre is a point of $P_0$ and whose radius is equal to the distance between some pair of points in $P_0$.

The ancient Greeks preferred a restricted version of the compasses operation; namely, draw a circle, centre some point of $P_0$, and pass through some other point
of $P_0$. Operation 2 can be performed by a sequence of such operations (see Exercise 7.11), so it ultimately makes no difference which version we use. The one given above is more convenient for our purposes.

**Definition 7.1** The points of intersection of any two distinct lines or circles drawn using the operations ruler and compasses, are said to be constructible in one step from $P_0$. More generally, a point $r \in \mathbb{R}^2$ is constructible from $P_0$ if there is a finite sequence $r_1, \ldots, r_n = r$ of points of $\mathbb{R}^2$, such that for each $j = 1, \ldots, n$ the point $r_j$ is constructible in one step from the set $P_0 \cup \{r_1, \ldots, r_{j-1}\}$.

**Example 7.2**
We show how the standard construction of the midpoint of a line segment can be realized within our formal framework. Suppose we are given two points $p_1, p_2 \in \mathbb{R}^2$ (Figure 7.2). Let $P_0 = \{p_1, p_2\}$.

1. Draw the line $p_1p_2$ (ruler).
2. Draw the circle centre $p_1$ of radius $p_1p_2$ (compasses).
3. Draw the circle centre $p_2$ of radius $p_1p_2$ (compasses).
4. Let $r_1$ and $r_2$ be the points of intersection of these circles.
5. Draw the line $r_1r_2$ (ruler).
6. Let $r_3$ be the intersection of the lines $p_1p_2$ and $r_1r_2$.

Then the sequence of points $r_1, r_2, r_3$ determines a construction of the midpoint of the line $p_1p_2$.

Because a line is always specified by two distinct points lying on it, and a circle by its centre and a point on its circumference, all the traditional geometrical constructions of Euclidean geometry fall within the scope of our formal definition.

The key idea for understanding the limitations of ruler-and-compass constructions is to relate them to field extensions. There is a natural way to do this. To each stage

![Figure 7.2: Bisecting a line segment with ruler and compasses.](image-url)
in the construction we associate the subfield of \( \mathbb{C} \) generated by the coordinates of the points constructed, which of course is actually a subfield of \( \mathbb{R} \). Thus let \( K_0 \) be the subfield of \( \mathbb{R} \) generated by the \( x \)- and \( y \)-coordinates of the points in \( P_0 \). If \( r_j \) has coordinates \((x_j, y_j)\), then inductively we define \( K_j \) to be the field obtained from \( K_{j-1} \) by adjoining \( x_j \) and \( y_j \), that is,

\[
K_j = K_{j-1}(x_j, y_j)
\]

The notation here may be confusing. We are not adjoining the point \((x_j, y_j)\) to \( K_{j-1} \) (which makes no sense); we are adjoining the set \( \{x_j, y_j\} \) formed by the two coordinates of that point.

Clearly, there is a tower of subfields

\[
K_0 \subseteq K_1 \subseteq \cdots \subseteq K_n \subseteq \mathbb{R}
\]

and we use this tower to derive a criterion for constructibility. The crucial result is relatively straightforward.

**Lemma 7.3**

With the above notation, \( x_j \) and \( y_j \) are zeros in \( K_j \) of quadratic polynomials over \( K_{j-1} \).

**Proof.** There are three cases to consider: line meets line, line meets circle, and circle meets circle. Each case is handled by coordinate geometry; as an example, we take the case line meets circle, Figure 7.3.

Let \( A, B, C \) be points whose coordinates \((p, q), (r, s), (t, u)\) lie in \( K_{j-1} \). Draw the line \( AB \) and the circle centre \( C \), radius \( w \), where \( w^2 \in K_{j-1} \) as in Figure 7.3. We know that \( w^2 \) lies in \( K_{j-1} \), since \( w \) is the distance between two points whose coordinates are in \( K_{j-1} \), and we can use Pythagoras. The equation of the line \( AB \) is

\[
\frac{x - p}{r - p} = \frac{y - q}{s - q}
\]

(7.1)

and the equation of the circle is

\[
(x - t)^2 + (y - u)^2 = w^2
\]

(7.2)

**Figure 7.3:** Line meets circle.
Solving Equations (7.1) and (7.2) we obtain

\[(x - t)^2 + \left( \frac{(s - q)}{(r - p)}(x - p) + q - u \right)^2 = w^2\]

so the \(x\)-coordinates of the intersection points \(X\) and \(Y\) are zeros of a quadratic polynomial over \(K_{j-1}\). The same holds for the \(y\)-coordinates.

If a subfield of \(\mathbb{C}\) is extended by adjoining the zeros of a quadratic polynomial, then the extension has degree 1 or 2. A geometric construction repeats this process several times. So we have an algebraic consequence of the existence of a construction for a given point.

**THEOREM 7.4**

If \(r = (x, y)\) is constructible from a subset \(P_0\) of \(\mathbb{R}^2\), and \(K_0\) is the subfield of \(\mathbb{R}\) generated by the coordinates of the points of \(P_0\), then the degrees

\[
[K_0(x) : K_0] \quad \text{and} \quad [K_0(y) : K_0]
\]

are powers of 2.

**PROOF** We use the notation that we have been accumulating. By Lemma 7.3 and Proposition 6.7,

\[
[K_{j-1}(x_j) : K_{j-1}] = 1 \text{ or } 2
\]

The value 2 occurs if the quadratic polynomial over \(K_{j-1}\) having \(x_j\) as a zero is irreducible, otherwise the value is 1. Similarly,

\[
[K_{j-1}(y_j) : K_{j-1}] = 1 \text{ or } 2
\]

Therefore, by the short tower law,

\[
[K_{j-1}(x_j, y_j) : K_{j-1}] = [K_{j-1}(x_j, y_j) : K_{j-1}(x_j)][K_{j-1}(x_j) : K_{j-1}]
\]

\[
= 1, 2, \text{ or } 4
\]

Actually, the value 4 never arises (see Exercise 7.12). This observation is not required for our argument, however, because either way \([K_j : K_{j-1}]\) is a power of 2. By the tower law, \([K_n : K_0]\) is a power of 2. But since

\[
[K_n : K_0(x)][K_0(x) : K_0] = [K_n : K_0]
\]

\([K_0(x) : K_0]\) is a power of 2. Similarly, \([K_0(y) : K_0]\) is a power of 2.
7.2 Impossibility Proofs

We now apply the above theory to prove that there do not exist ruler-and-compass constructions that solve the three classical problems mentioned in the introduction to this chapter. For the technical drawing expert we emphasize that we are discussing exact constructions. There are many approximate constructions for trisecting the angle, for instance; but no exact methods. Dudley (1987) is a fascinating collection of approximate methods that were thought by their inventors to be exact. Here’s one (Figure 7.4). To trisect angle BOA, draw line BE parallel to OA. Mark off AC and CD equal to OA, draw arc DE with centre C and radius CD. Drop a perpendicular EF to OD and draw arc FT centre O radius OF to meet BE at T. Then angle AOT approximately trisects angle BOA (see Exercise 7.10).

The simplest problem to resolve is duplicating the cube. Its impossibility was first demonstrated by Gauss’s student Pierre Wantzel in 1837.

**THEOREM 7.5 (Wantzel)**
The cube cannot be duplicated using ruler-and-compass constructions.

**PROOF** We are given a cube, and hence a side of the cube, which we may take to be the unit interval on the $x$-axis. Therefore, we may assume that $P_0 = \{(0, 0), (1, 0)\}$ so that $K_0 = \mathbb{Q}$. The other distances between vertices of the cube are then $\sqrt{2}$ and $\sqrt{3}$, which are constructible from $P_0$ anyway. If we could duplicate the cube, then we could construct the point $(\alpha, 0)$ where $\alpha^3 = 2$. Therefore, by Theorem 7.4, $[\mathbb{Q}(\alpha) : \mathbb{Q}]$ would be a power of 2. But $\alpha$ is a zero of the polynomial $r^3 - 2$ over $\mathbb{Q}$, and this is irreducible over $\mathbb{Q}$ by Eisenstein’s criterion. Hence $r^3 - 2$ is the minimal polynomial of $\alpha$ over $\mathbb{Q}$, and by Proposition 6.7, $[\mathbb{Q}(\alpha) : \mathbb{Q}] = 3$. Since 3 is not a power of 2, this is a contradiction. Therefore, the cube cannot be duplicated.

In the same 1837 paper, Wantzel also proved that trisection of the angle is demolished by a similar argument. Of course, *some* angles can be trisected ($\pi$ and $\pi/2$ are examples), but not all. In particular:
7.2 Impossibility Proofs

Figure 7.5: Trisecting π/3.

THEOREM 7.6 (Wantzel)
The angle π/3 cannot be trisected using ruler-and-compass constructions.

PROOF It is easy to construct the angle π/3 starting from (0, 0) and (1, 0). Therefore, to trisect π/3 is equivalent to starting from (0, 0) and (1, 0), and constructing the point (α, 0), where α = cos(π/9) (see Figure 7.5). From this we can construct (β, 0) where β = 2 cos(π/9). From elementary trigonometry, recall the formula

\[ \cos 3\theta = 4 \cos^3 \theta - 3 \cos \theta \]

If we put θ = π/9, then cos 3θ = \( \frac{1}{2} \), and β satisfies the cubic

\[ \beta^3 - 3\beta - 1 = 0 \]

Now \( f(t) = t^3 - 3t - 1 \) is irreducible over \( \mathbb{Q} \), since

\[ f(t + 1) = t^3 + 3t^2 - 3 \]

is irreducible by Eisenstein’s criterion. As in the previous theorem, \([\mathbb{Q}(\beta) : \mathbb{Q}] = 3\), a contradiction.

This is the place for a word of warning to would-be trisectors, who are often aware of Wantzel’s impossibility proof but somehow imagine that they can succeed despite it (Dudley, 1987). If you claim a trisection of a general angle using ruler and compasses according to our standing conventions (such as unmarked ruler), then you are in particular claiming a trisection of π/3 using those instruments. The above proof shows that you are, therefore, claiming that 3 is a power of 2; in particular, since 3 \( \neq 1 \), you are claiming that 3 is an even number.

Do you really want to go down in history as believing you have proved this?
The final problem of antiquity is more difficult:

THEOREM 7.7
The circle cannot be squared using ruler-and-compass constructions.
PROOF Such a construction is equivalent to constructing the point \((0, \sqrt{\pi})\) from the initial set of points \(P_0 = \{(0, 0), (1, 0)\}\). From this we can easily construct \((0, \pi)\). So if such a construction exists, then \([\mathbb{Q}(\pi) : \mathbb{Q}]\) is a power of 2 and, in particular, \(\pi\) is algebraic over \(\mathbb{Q}\). On the other hand, a famous theorem of Ferdinand Lindemann asserts that \(\pi\) is not algebraic over \(\mathbb{Q}\). The theorem follows.

We prove Lindemann’s theorem in Chapter 24. The proof involves ideas off the main track of the book and has, therefore, been placed in the final chapter. The reader who is willing to take the result on trust can skip the proof; the results are not used anywhere else in the book.

Exercises

7.1 Express in the language of this chapter methods of constructing, by ruler and compasses:
   a. The perpendicular bisector of a line
   b. The points trisecting a line
   c. Division of a line into \(n\) equal parts
   d. The tangent to a circle at a given point
   e. Common tangents to two circles

7.2 Estimate the degrees of the field extensions corresponding to the constructions in Exercise 7.1 by giving reasonably good upper bounds.

7.3 Prove using Euclidean geometry that the marked ruler construction of Figure 7.1 does indeed trisect the given angle AOB.

7.4 Can the angle \(2\pi/5\) be trisected using ruler and compasses?

7.5 Show that it is impossible to construct a regular 9-gon using ruler and compasses.

7.6 By considering a formula for \(\cos 5\theta\) find a construction for the regular pentagon.

7.7 Prove that the angle \(\theta\) can be trisected by ruler and compasses if and only if the polynomial

\[
4t^3 - 3t - \cos \theta
\]

is reducible over \(\mathbb{Q}(\cos \theta)\).

7.8 Discuss the quinquisection (division into five equal parts) of angles.
Figure 7.6:  Srinivasa Ramanujan's approximate squaring of the circle.

7.9 Verify the following approximate construction for $\pi$ due to Ramanujan (1962, p. 35) (see Figure 7.6). Let $AB$ be the diameter of a circle centre $O$. Bisect $AO$ at $M$, trisect $OB$ at $T$. Draw $TP$ perpendicular to $AB$, meeting the circle at $P$. Draw $BQ = PT$, and join $AQ$. Draw $OS$, $TR$ parallel to $BQ$. Draw $AD = AS$, and $AC = RS$ tangential to the circle at $A$. Join $BC$, $BD$, $CD$. Make $BE = BM$. Draw $FX$ parallel to $CD$. Then the square on $RX$ has approximately the same area as the circle.

(You will need to know that $\pi$ is approximately $\frac{355}{113}$. This approximation is first found in the works of the Chinese astronomer Tsu Ch'ung Ching in about 450 AD.)

7.10 Prove that the construction in Figure 7.4 is correct if and only if the identity

$$\frac{\sin \frac{\theta}{3}}{\sin \frac{\theta}{2 + \cos \theta}}$$

holds. Disprove the identity and estimate the error in the construction.

7.11 Show that the compasses operation can be replaced by draw a circle centre $P_0$ and pass through some other point of $P_0$ without altering the set of constructible points.

7.12 In the proof of Theorem 7.4, show that in fact $[K_{j-1} (x_j, y_j) : K_{j-1}]$ is 1 or 2. (Hint: Show that $x_j$ and $y_j$ belong to the same quadratic extension of $K_{j-1}$.)

7.13 Show that the regular heptagon (7-sided polygon) cannot be constructed with ruler and compasses. Hint: To construct the regular 7-gon is equivalent to solving the polynomial equation

$$f(t) = t^6 + t^5 + t^4 + t^3 + t^2 + t + 1 = 0$$
Figure 7.7: Duplicating the cube using a marked ruler.

whose roots include $\cos \frac{2\pi}{7} + i \sin \frac{2\pi}{7}$. Substitute $u = t + \frac{1}{t}$ to get a cubic. Prove that this cubic is irreducible.

Alternatively, prove that $f$ is irreducible.

7.14 A race of alien creatures living in $n$-dimensional hyperspace $\mathbb{R}^n$ wishes to duplicate the hypercube by ruler-and-compass construction. For which $n$ can they succeed?

7.15 Figure 7.7 shows a regular hexagon and some related lines. If $XY = 1$, show that $YB = \sqrt{2}$. Deduce that the cube can be duplicated using a marked ruler.

7.16 Since the angles $\theta, \theta + \frac{2\pi}{3}, \theta + \frac{4\pi}{3}$ are all equal, it can be argued that every angle has three distinct trisections. Show that Archimedes’s construction with a marked ruler (Figure 7.1) can find them all.

7.17 Mark the following true or false.

a. There exist ruler-and-compass constructions trisecting the angle to an arbitrary degree of approximation.

b. Such constructions are sufficient for practical purposes but insufficient for mathematical ones.

c. The coordinates of a constructible point lie in a subfield of $\mathbb{R}$ whose degree over the subfield generated by the coordinates of the given points is a power of 2.

d. The angle $\pi$ cannot be trisected using ruler and compasses.

e. A line of length $\pi$ cannot be constructed from $\{(0, 0), (1, 0)\}$ using ruler and compasses.

f. It is impossible to triplicate the cube by ruler and compasses.

g. The real number $\pi$ is transcendental over $\mathbb{Q}$.

h. The real number $\pi$ is transcendental over $\mathbb{R}$.

i. If $(0, \alpha)$ cannot be constructed from $\{(0, 0), (1, 0)\}$ by ruler and compasses, then $\alpha$ is transcendental over $\mathbb{Q}$. 
Chapter 8

The Idea Behind Galois Theory

Having satisfied ourselves that field extensions are good for something, we can return to the main theme: the elusive quintic and Galois’s deep insights into the solubility of equations by radicals. We start by outlining the main theorem that we wish to prove, and the steps required to prove it. And, more importantly, we explain where it came from.

We have already associated a vector space to each field extension. For some problems this is too coarse an instrument; it measures the size, but not the shape, so to speak. Galois went deeper into the structure. To any polynomial $p \in \mathbb{C}[x]$, he associated a group of permutations, now called the Galois group of $p$ in his honour. Complicated questions about the polynomial can sometimes be reduced to much simpler questions about the group, especially when it comes to solution by radicals. What makes his work so astonishing is that at the time the group concept existed only in rudimentary form. Galois was the first to recognize its importance.

We introduce the main ideas in a very simple context: a quartic polynomial equation whose roots are obvious. We show that the reason for the roots being obvious can be stated in terms of the symmetries of the polynomial — in an appropriate sense — and that any polynomial equation with those symmetries will also have obvious roots.

With a little extra effort, we then subvert the entire reason for the existence of this book by proving that the general polynomial equation of the $n$th degree cannot be solved by radicals of a particular, special kind when $n \geq 5$. This is a spectacular application of the Galois group, but in a very limited context; it corresponds roughly to what Ruffini proved (or came close to proving) in 1813. By stealing one further idea from Abel, we can even remove Ruffini’s assumption, and prove that there is no general radical expression in the coefficients of a quintic, or any polynomial of degree $\geq 5$, that determines a zero.

We could stop there. But Galois went much further; his methods are not only more elegant, they give much stronger results. The material in this chapter provides a springboard from which we can launch into the full beauty of the theory.

8.1 A First Look at Galois Theory

Galois theory is a fascinating mixture of classical and modern mathematics, and it takes a certain amount of effort to get used to its thought patterns. This section is
intended to give a quick survey of the basic principles of the subject, and explain how the abstract treatment has developed from Galois's original ideas.

The aim of Galois theory is to study the solutions of polynomial equations

\[ f(t) = t^n + a_{n-1}t^{n-1} + \cdots + a_0 = 0 \]

and, in particular, to distinguish those that can be solved by a formula from those that cannot. By a formula we mean a radical expression, anything that can be built up from the coefficients \( a_j \) by the operations of addition, subtraction, multiplication, and division, and also — the essential ingredient — by \( n \)th roots, \( n = 2, 3, 4, \ldots \).

The central objective of the book is a proof that, unlike quadratic, cubic, and quartic equations, the quintic equation cannot, in general, be solved by such a formula. Along the way we also find out why quadratics, cubics, and quartics can be solved using radicals.

In modern terms, Galois's main idea is to look at the symmetries of the polynomial \( f(t) \). These form a group, its Galois group, and the solution of the polynomial equation is reflected in various properties of the Galois group.

---

### 8.2 Galois Groups According to Galois

Galois had to invent the concept of a group, quite aside from sorting out how it relates to the solution of equations. Not surprisingly, his approach was relatively concrete by today's standards, but by those of his time, it was highly abstract. Indeed, Galois is one of the founders of modern abstract algebra. So to understand the modern approach, it helps to take a look at something rather closer to what Galois had in mind.

As an example, consider the polynomial equation

\[ f(t) = t^4 - 4t^2 - 5 = 0 \]

which we encountered in Chapter 4. As we saw, this factorizes as

\[ (t^2 + 1)(t^2 - 5) = 0 \]

so there are four roots \( t = i, -i, \sqrt{5}i, -\sqrt{5}i \). These form two natural pairs: \( i \) and \(-i\) go together, and so do \( \sqrt{5}i \) and \(-\sqrt{5}i \). Indeed, it is impossible to distinguish \( i \) from \(-i\), or \( \sqrt{5}i \) from \(-\sqrt{5}i \), by algebraic means, in the following sense. Write down any polynomial equation with rational coefficients that is satisfied by some selection from the four roots. If we let

\[ \alpha = i \quad \beta = -i \quad \gamma = \sqrt{5} \quad \delta = -\sqrt{5} \]

then such equations include

\[ \alpha^2 + 1 = 0 \quad \alpha + \beta = 0 \quad \delta^2 - 5 = 0 \quad \gamma + \delta = 0 \quad \alpha\gamma - \beta\delta = 0 \]
and so on. There are infinitely many valid equations of this kind. On the other hand, infinitely many other algebraic equations, such as $\alpha + \gamma = 0$, are manifestly false.

Experiment suggests that if we take any valid equation connecting $\alpha$, $\beta$, $\gamma$, and $\delta$, and interchange $\alpha$ and $\beta$, we again get a valid equation. The same is true if we interchange $\gamma$ and $\delta$. For example, the above equations lead by this process to

\[
\begin{align*}
\beta^2 + 1 &= 0 \\
\beta + \alpha &= 0 \\
\gamma^2 - 5 &= 0 \\
\delta + \gamma &= 0 \\
\beta \gamma - \alpha \delta &= 0 \\
\alpha \delta - \beta \gamma &= 0 \\
\beta \delta - \alpha \gamma &= 0
\end{align*}
\]

and all of these are valid. In contrast, if we interchange $\alpha$ and $\gamma$, we obtain equations such as

\[
\begin{align*}
\gamma^2 + 1 &= 0 \\
\gamma + \beta &= 0 \\
\alpha + \delta &= 0
\end{align*}
\]

which are false.

The operations that we are using here are permutations of the zeros $\alpha$, $\beta$, $\gamma$, $\delta$. In fact, in the usual permutation notation, the interchange of $\alpha$ and $\beta$ is

\[
R = \begin{pmatrix}
\alpha & \beta & \gamma & \delta \\
\beta & \alpha & \gamma & \delta
\end{pmatrix}
\]

and that of $\gamma$ and $\delta$ is

\[
S = \begin{pmatrix}
\alpha & \beta & \gamma & \delta \\
\alpha & \beta & \delta & \gamma
\end{pmatrix}
\]

These are elements of the symmetric group $S_4$ on four symbols, which includes all 24 possible permutations of $\alpha$, $\beta$, $\gamma$, $\delta$.

If these two permutations turn valid equations into valid equations, then so must the permutation obtained by performing them both in turn, which is

\[
T = \begin{pmatrix}
\alpha & \beta & \gamma & \delta \\
\beta & \alpha & \delta & \gamma
\end{pmatrix}
\]

Are there any other permutations that preserve all the valid equations? Yes, of course, the identity

\[
I = \begin{pmatrix}
\alpha & \beta & \gamma & \delta \\
\alpha & \beta & \gamma & \delta
\end{pmatrix}
\]

It can be checked that only these four permutations preserve valid equations; the other 20 all turn some valid equation into a false one.

It is a general fact, and an easy one to prove, that the invertible transformations of a mathematical object that preserve some feature of its structure always form a group. We call this the symmetry group of the object. This terminology is especially common when the object is a geometrical figure and the transformations are rigid motions, but
the same idea applies more widely. And indeed, these four permutations do form a

group, which we denote by \( G \).

What Galois realized is that the structure of this group to some extent controls how
we should set about solving the equation.

He did not use today’s notation for permutations, and this led to potential confusion.
To him, a permutation of, say, \( \{1, 2, 3, 4, 5\} \), was an ordered list, such as 25413. Given
a second list, say 32154, he then considered the substitution that changes 25413 to
32154; that is, the map \( 2 \mapsto 3, 5 \mapsto 2, 4 \mapsto 1, 1 \mapsto 5, 3 \mapsto 4 \). Nowadays we would write this as

\[
\begin{pmatrix}
2 & 5 & 4 & 1 & 3 \\
3 & 2 & 1 & 5 & 4
\end{pmatrix}
\]

or, reordering the top row,

\[
\begin{pmatrix}
1 & 2 & 3 & 4 & 5 \\
5 & 3 & 4 & 1 & 2
\end{pmatrix}
\]

but Galois did not even have the \( \mapsto \) notation or associated concepts, so he had to
write the substitution as 53412. His use of similar notation for both permutations and
substitutions takes some getting used to, and probably did not make life easier for the
people asked to referee his papers. Today’s definition of function or map dates from
about 1950; it certainly helps to clarify the ideas.

To see why permutations/substitutions of the roots matter, consider the subgroup
\( H = \{I, R\} \) of \( G \). Certain expressions in \( \alpha, \beta, \gamma, \delta \) are fixed by the permutations in this
group. For example, if we apply \( R \) to \( \alpha^2 + \beta^2 - 5 \gamma \delta^2 \), then we obtain \( \beta^2 + \alpha^2 - 5 \gamma \delta^2 \),
which is clearly the same. In fact, an expression is fixed by \( R \) if and only if it is
symmetric in \( \alpha \) and \( \beta \).

It is not hard to show that any polynomial in \( \alpha, \beta, \gamma, \delta \) that is symmetric in \( \alpha \) and
\( \beta \) can be rewritten as a polynomial in \( \alpha + \beta, \alpha \beta, \gamma, \) and \( \delta \). For example, the above
expression can be written as \( (\alpha + \beta)^2 - 2 \alpha \beta - 5 \gamma \delta^2 \). But we know that \( \alpha = i, \beta = -i \),
so that \( \alpha + \beta = 0 \) and \( \alpha \beta = 1 \). Hence the expression reduces to \( -2 - 5 \gamma \delta^2 \). Now \( \alpha \)
and \( \beta \) have been eliminated altogether.

---

8.3 And How to Use Them

Pretend for a moment that we don’t know the explicit zeros \( i, -i, \sqrt{5}, -\sqrt{5} \), but
that we do know the Galois group \( G \). In fact, consider any quartic polynomial \( g(t) \)
with the same Galois group as our example \( f(t) \) above; that way we cannot possibly
know the zeros explicitly. Let them be \( \alpha, \beta, \gamma, \delta \). Consider three subfields of \( \mathbb{C} \) related
to \( \alpha, \beta, \gamma, \delta \), namely,

\[
\mathbb{Q} \subset \mathbb{Q}(\gamma, \delta) \subset \mathbb{Q}(\alpha, \beta, \gamma, \delta)
\]
Let $H = \{I, R\} \subseteq G$. Assume that we also know the following two facts:

1. The numbers fixed by $H$ are precisely those in $\mathbb{Q}(\gamma, \delta)$.

2. The numbers fixed by $G$ are precisely those in $\mathbb{Q}$.

Then we can work out how to solve the quartic equation $g(t) = 0$, as follows.

The numbers $\alpha + \beta$ and $\alpha \beta$ are obviously both fixed by $H$. By fact (1) they lie in $\mathbb{Q}(\gamma, \delta)$. But since

$$(t - \alpha)(t - \beta) = t^2 - (\alpha + \beta)t + \alpha \beta$$

this means that $\alpha$ and $\beta$ satisfy a quadratic equation whose coefficients are in $\mathbb{Q}(\gamma, \delta)$. That is, we can use the formula for solving a quadratic to express $\alpha, \beta$ in terms of rational functions of $\gamma$ and $\delta$, together with nothing worse than square roots. Thus we obtain $\alpha$ and $\beta$ as radical expressions in $\gamma$ and $\delta$.

But we can repeat the trick to find $\gamma$ and $\delta$. The numbers $\gamma + \delta$ and $\gamma \delta$ are fixed by the whole of $G$; they are clearly fixed by $R$, and also by $S$, and these generate $G$. Therefore, $\gamma + \delta$ and $\gamma \delta$ belong to $\mathbb{Q}$ by fact (2) above. Therefore, $\gamma$ and $\delta$ satisfy a quadratic equation over $\mathbb{Q}$, so they are given by radical expressions in rational numbers. Plugging these into the formulas for $\alpha$ and $\gamma$ we find that all four zeros are radical expressions in rational numbers.

We have not found the formulas explicitly, but we have shown that certain information about the Galois group necessarily implies that they exist. Given more information, we can finish the job completely.

This example illustrates that the subgroup structure of the Galois group $G$ is closely related to the possibility of solving the equation $g(t) = 0$. Galois discovered that this relationship is very deep and detailed. For example, his proof that an equation of the fifth degree cannot be solved by a formula boils down to this: the quintic has the wrong sort of Galois group. We present a simplified version of this argument, in a restricted setting, in Section 8.7. In Section 8.8 we remove this technical restriction using Abel's classical methods.

---

### 8.4 The Abstract Setting

The modern approach follows Galois closely in principle, but differs in several respects in practice. The permutations of $\alpha$, $\beta$, $\gamma$, $\delta$ that preserve all algebraic relations between them turn out to be the symmetry group of the subfield $\mathbb{Q}(\alpha, \beta, \gamma, \delta)$ of $\mathbb{C}$ generated by the zeros of $g$, or more precisely its automorphism group, which is a fancy name for the same thing.

Moreover, we wish to consider polynomials not just with integer or rational coefficients, but coefficients that lie in a subfield $K$ of $\mathbb{C}$ (or, later, any field). The zeros of a polynomial $f(t)$ with coefficients in $K$ determine another field $L$ which contains $K$, but may well be larger. Thus, the primary object of consideration is a pair of fields
The Idea Behind Galois Theory

$K \subset L$, or in a slight generalization, a field extension $L : K$. Thus, when Galois talks of polynomials, the modern approach talks of field extensions. And the Galois group of the polynomial becomes the group of $K$-automorphisms of $L$, that is, of maps $\theta : L \to L$ such that for all $x, y \in L$ and $k \in K$

\[
\theta(x + y) = \theta(x) + \theta(y)
\]

\[
\theta(xy) = \theta(x)\theta(y)
\]

\[
\theta(k) = k
\]

Thus, the bulk of the theory is described in terms of field extensions and their groups of $K$-automorphisms. This point of view was introduced in 1894 by Dedekind, who also gave axiomatic definitions of subrings and subfields of $\mathbb{C}$.

The method used above to solve $g(t) = 0$ relies crucially on knowing (1) and (2). But can we lay our hands on that kind of information if we do not already know the zeros of $g$? The answer is that we can — though not easily — provided we make a general study of the automorphism groups of field extensions, their subgroups, and the subfields fixed by those subgroups. This study leads to the Galois correspondence between subgroups of the Galois group and subfields $M$ of $L$ that contain $K$. Chapters 9 to 11 set up the Galois correspondence and prove its key properties, and the main theorem is stated and proved in Chapter 12. Chapter 13 studies one example in detail to drive the ideas home. Chapters 15 and 18 derive the spectacular consequences for the quintic. Then, starting in Chapter 16, we generalize the Galois correspondence to arbitrary fields, and develop the resulting theory in several directions.

8.5 Polynomials and Extensions

In this section we define the Galois group of a field extension $L : K$. We begin by defining a special kind of automorphism.

**Definition 8.1** Let $L : K$ be a field extension, so that $K$ is a subfield of the subfield $L$ of $\mathbb{C}$. A $K$-automorphism of $L$ is an automorphism $\alpha$ of $L$ such that

\[
\alpha(k) = k \quad \text{for all } k \in K
\]

(8.1)

We say that $\alpha$ fixes $k \in K$ if (8.1) holds.

Effectively, condition (8.1) makes $\alpha$ an automorphism of the extension $L : K$, rather than an automorphism of the large field $L$ alone. The idea of considering automorphisms of a mathematical object relative to a subobject is a useful general method; it falls within the scope of the famous 1872 Erlangen Programme of Felix Klein. Klein's idea was to consider every geometry as the theory of invariants of an
8.5 Polynomials and Extensions

associated transformation group. Thus, Euclidean geometry is the study of invariants of the group of distance-preserving transformations of the plane, projective geometry arises if we allow projective transformations, and topology comes from the group of all continuous maps possessing continuous inverses (called homeomorphisms or topological transformations). According to this interpretation any field extension is a geometry, and we are simply studying the geometrical figures.

The pivot upon which the whole theory turns is a result that is not in itself hard to prove. As Lewis Carroll said in *The Hunting of the Snark*, it is a "maxim tremendous but trite."

**THEOREM 8.2**

If \( L : K \) is a field extension, then the set of all \( K \)-automorphisms of \( L \) forms a group under composition of maps.

**PROOF** Suppose that \( \alpha \) and \( \beta \) are \( K \)-automorphisms of \( L \). Then \( \alpha \beta \) is clearly an automorphism; further, if \( k \in K \), then \( \alpha \beta(k) = \alpha(\beta(k)) = k \) so that \( \alpha \beta \) is a \( K \)-automorphism. The identity map on \( L \) is obviously a \( K \)-automorphism. Finally, \( \alpha^{-1} \) is an automorphism of \( L \), and for any \( k \in K \) we have

\[
k = \alpha^{-1}(\alpha(k)) = \alpha^{-1}(k)
\]

so that \( \alpha^{-1} \) is a \( K \)-automorphism. Composition of maps is associative, so the set of all \( K \)-automorphisms of \( L \) is a group. □

**DEFINITION 8.3** The Galois group \( \Gamma(L : K) \) of a field extension \( L : K \) is the group of all \( K \)-automorphisms of \( L \) under the operation of composition of maps.

**Example 8.4**

1. The extension \( \mathbb{C} : \mathbb{R} \). Suppose that \( \alpha \) is an \( \mathbb{R} \)-automorphism of \( \mathbb{C} \). Let \( j = \alpha(i) \) where \( i = \sqrt{-1} \). Then

\[
j^2 = (\alpha(i))^2 = \alpha(i^2) = \alpha(-1) = -1
\]

since \( \alpha(r) = r \) for all \( r \in \mathbb{R} \). Hence, either \( j = i \) or \( j = -i \). Now, for any \( x, y \in \mathbb{R} \)

\[
\alpha(x + iy) = \alpha(x) + \alpha(i)\alpha(y) = x + jy
\]

Thus we have two candidates for \( \mathbb{R} \)-automorphisms:

\[
\alpha_1 : x + iy \mapsto x + iy
\]
\[
\alpha_2 : x + iy \mapsto x - iy
\]
Obviously, \(\alpha_1\) is the identity, and thus is an \(\mathbb{R}\)-automorphism of \(C\). The map \(\alpha_2\) is complex conjugation, and is an automorphism by Example 1.4(1). Moreover,

\[ \alpha_2(x + 0i) = x - 0i = x \]

so \(\alpha_2\) is an \(\mathbb{R}\)-automorphism. Obviously, \(\alpha_2^2 = \alpha_1\), so the Galois group \(\Gamma(C: \mathbb{R})\) is a cyclic group of order 2.

2. Let \(c\) be the real cube root of 2, and consider \(\mathbb{Q}(c) : \mathbb{Q}\). If \(\alpha\) is a \(\mathbb{Q}\)-automorphism of \(\mathbb{Q}(c)\), then

\[ (\alpha(c))^3 = \alpha(c^3) = \alpha(2) = 2 \]

Since \(\mathbb{Q}(c) \subset \mathbb{R}\) we must have \(\alpha(c) = c\). Hence \(\alpha\) is the identity map, and \(\Gamma(\mathbb{Q}(c) : \mathbb{Q})\) has order 1.

3. Let the field extension be \(\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5}) : \mathbb{Q}\) as in Example 8. The analysis presented in that example shows that \(t^2 - 5\) is irreducible over \(\mathbb{Q}(\sqrt{2}, \sqrt{3})\). Similarly, \(t^2 - 2\) is irreducible over \(\mathbb{Q}(\sqrt{3}, \sqrt{5})\) and \(t^2 - 3\) is irreducible over \(\mathbb{Q}(\sqrt{2}, \sqrt{5})\). Thus, there are three \(\mathbb{Q}\)-automorphisms of \(\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})\) defined by

\[
\begin{align*}
\rho_2 : \sqrt{2} &\mapsto -\sqrt{2} & \sqrt{3} &\mapsto \sqrt{3} & \sqrt{5} &\mapsto \sqrt{5} \\
\rho_3 : \sqrt{2} &\mapsto \sqrt{2} & \sqrt{3} &\mapsto -\sqrt{3} & \sqrt{5} &\mapsto \sqrt{5} \\
\rho_5 : \sqrt{2} &\mapsto \sqrt{2} & \sqrt{3} &\mapsto \sqrt{3} & \sqrt{5} &\mapsto -\sqrt{5}
\end{align*}
\]

It is easy to see that these maps commute, and hence generate the group \(\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2\). Moreover, any \(\mathbb{Q}\)-automorphism of \(\mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5})\) must map \(\sqrt{2} \mapsto \pm\sqrt{2}, \sqrt{3} \mapsto \pm\sqrt{3},\) and \(\sqrt{5} \mapsto \pm\sqrt{5}\) by considering minimal polynomials. All combinations of signs occur in the group \(\mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2\), so this must be the Galois group.

---

### 8.6 The Galois Correspondence

Although it is easy to prove that the set of all \(K\)-automorphisms of a field extension \(L : K\) forms a group, that fact alone does not significantly advance the subject. To be of any use, the Galois group must reflect aspects of the structure of \(L : K\). Galois made the discovery (which he expressed in terms of polynomials) that, under certain extra hypotheses, there is a one-to-one correspondence between:

1. Subgroups of the Galois group of \(L : K\)
2. Subfields \(M\) of \(L\) such that \(K \subseteq M\)

As it happens, this correspondence reverses inclusion relations: larger subfields correspond to smaller groups. First, we explain how the correspondence is set up.
If \( L : K \) is a field extension, we call any field \( M \) such that \( K \subseteq M \subseteq L \) is an intermediate field. To each intermediate field \( M \) we associate the group \( M^* = \Gamma(L : M) \) of all \( M \)-automorphisms of \( L \). Thus \( K^* \) is the whole Galois group, and \( L^* = 1 \) (the group consisting of just the identity map on \( L \)). Clearly, if \( M \subseteq N \), then \( M^* \supseteq N^* \) because any automorphism of \( L \) that fixes the elements of \( N \) certainly fixes the elements of \( M \). This is what we mean by reverses inclusions.

Conversely, to each subgroup \( H \) of \( \Gamma(L : K) \) we associate the set \( H^\dagger \) of all elements \( x \in L \) such that \( \alpha(x) = x \) for all \( \alpha \in H \). In fact, this set is an intermediate field.

**Lemma 8.5**

If \( H \) is a subgroup of \( \Gamma(L : K) \), then \( H^\dagger \) is a subfield of \( L \) containing \( K \).

**Proof** Let \( x, y \in H^\dagger \), and \( \alpha \in H \). Then
\[
\alpha(x + y) = \alpha(x) + \alpha(y) = x + y
\]
so \( x + y \in H^\dagger \). Similarly, \( H^\dagger \) is closed under subtraction, multiplication, and division (by nonzero elements), so \( H^\dagger \) is a subfield of \( L \). Since \( \alpha \in \Gamma(L : K) \) we have \( \alpha(k) = k \) for all \( k \in K \), so \( K \subseteq H^\dagger \).

**Definition 8.6** With the above notation, \( H^\dagger \) is the fixed field of \( H \).

It is easy to see that like \( * \), the map \( \dagger \) reverses inclusions: if \( H \subseteq G \), then \( H^\dagger \supseteq G^\dagger \).

It is also easy to verify that if \( M \) is an intermediate field and \( H \) is a subgroup of the Galois group, then
\[
M \subseteq M^{*\dagger} \\
H \subseteq H^{\dagger*}
\]
(8.2)

Indeed, every element of \( M \) is fixed by every automorphism that fixes all of \( M \), and every element of \( H \) fixes those elements that are fixed by all of \( H \). Example 8.4(2) shows that these inclusions are not always equalities, for there
\[
\mathbb{Q}^{*\dagger} = \mathbb{Q}(c) \neq \mathbb{Q}
\]

If we let \( \mathcal{F} \) denote the set of intermediate fields, and \( \mathcal{G} \) the set of subgroups of the Galois group, then we have defined two maps
\[
* : \mathcal{F} \to \mathcal{G} \\
\dagger : \mathcal{G} \to \mathcal{F}
\]

which reverse inclusions and satisfy equation (8.2). These two maps constitute the Galois correspondence between \( \mathcal{F} \) and \( \mathcal{G} \). Galois's results can be interpreted as giving conditions under which \( * \) and \( \dagger \) are mutual inverses, setting up a bijection between \( \mathcal{F} \) and \( \mathcal{G} \). The extra conditions needed are called separability (which is automatic over \( \mathbb{C} \)) and normality. They are discussed in Chapter 9.
**Example 8.7**

The polynomial equation

$$f(t) = t^4 - 4t^2 - 5 = 0$$

was discussed in Section 8.2. Its roots are $\alpha = i$, $\beta = -i$, $\gamma = \sqrt{5}$, $\delta = -\sqrt{5}$. The associated field extension is $L : \mathbb{Q}$ where $L = \mathbb{Q}(i, \sqrt{5})$, which we discussed in Example 4.8. There are four $\mathbb{Q}$-automorphisms of $L$, namely, $I, R, S, T$ where $I$ is the identity, and in cycle notation $R = (\alpha \beta)$, $S = (\gamma \delta)$, and $T = (\alpha \beta)(\gamma \delta)$. Recall that a cycle $(a_1 \ldots a_k) \in S_n$ is the permutation $\sigma$ such that $\sigma(a_j) = a_{j+1}$ when $1 \leq j \leq k - 1$, $\sigma(a_k) = a_1$, and $\sigma(a) = a$ when $a \not\in \{a_1, \ldots, a_k\}$. Every element of $S_n$ is a product of disjoint cycles, which commute, and this expression is unique except for the order in which the cycles are composed.

In fact, $I, R, S, T$ are all possible $\mathbb{Q}$-automorphisms of $L$, because any $\mathbb{Q}$-automorphism must send $i$ to $\pm i$ and $\sqrt{5}$ to $\pm \sqrt{5}$. Therefore, the Galois group is

$$G = \{I, R, S, T\}$$

The proper subgroups of $G$ are

$$1 \quad \{I, R\} \quad \{I, S\} \quad \{I, T\}$$

where $1 = \{I\}$. It is easy to check that the corresponding fixed fields are, respectively,

$$L \quad \mathbb{Q}(\sqrt{5}) \quad \mathbb{Q}(i) \quad \mathbb{Q}(i\sqrt{5})$$

Extensive but routine calculations (Exercise 7.1) show that these, together with $K$, are the only subfields of $L$. So, in this case, the Galois correspondence is bijective.

### 8.7 Diet Galois

To provide further motivation, we now pursue a modernized version of Lagrange's train of thought in his memoir of 1770–1771, which paved the way for Galois. Indeed, we will follow a line of argument that is very close to the work of Ruffini and Abel, and prove that the general quintic is not solvable by radicals. Why, then, does the rest of this book exist? Because "general" has a paradoxically special meaning in this context, and we have to place a very strong restriction on the kind of radical that is permitted. A major feature of Galois theory is that it does not assume this restriction. However, quadratics, cubics, and quartics are soluble by these restricted types of radical, so the discussion here does have some intrinsic merit. It could profitably be included as an application in a first course of group theory, or a digression in a course on rings and fields.

We have already encountered the symmetric group $S_n$, which comprises all permutations of the set $\{1, 2, \ldots, n\}$. It has a subgroup of index 2, the *alternating group* $A_n$. 
which consists of all products of an even number of transpositions \((ab)\). The elements of \(A_n\) are the even permutations. The group \(A_n\) is a normal subgroup of \(S_n\). It is well known that \(A_n\) is generated by all 3-cycles \((abc)\) (see Exercise 8.6). The group \(A_5\) holds the secret of the quintic, as we now explain.

Let \(t_1, \ldots, t_n\) be independent complex variables, and consider the polynomial

\[
F(t) = (t - t_1) \cdots (t - t_n)
\]

whose zeros are \(t_1, \ldots, t_n\). Expanding and using induction, we see that

\[
F(t) = t^n - s_1 t^{n-1} + s_2 t^{n-2} + \cdots + (-1)^n s_n
\]

where the \(s_j\) are the elementary symmetric polynomials

\[
\begin{align*}
    s_1 &= t_1 + \cdots + t_n \\
    s_2 &= t_1 t_2 + t_1 t_3 + \cdots + t_{n-1} t_n \\
    \vdots \\
    s_n &= t_1 \cdots t_n
\end{align*}
\]

Define

\[
L = \mathbb{C}(t_1, \ldots, t_n)
\]

which is the set of all rational functions of the \(t_j\). The symmetric group \(S_n\) acts as symmetries of \(L\):

\[
\sigma f(t_1, \ldots, t_n) = f(t_{\sigma(1)}, \ldots, t_{\sigma(n)})
\]

for \(f \in L\). The fixed field \(K\) of \(S_n\) consists, by definition, of all symmetric rational functions in the \(t_j\), which is known to be generated by the \(n\) elementary symmetric polynomials in the \(t_j\). That is, \(K = \mathbb{C}(s_1, \ldots, s_n)\). Moreover, the \(s_j\) satisfy no non-trivial polynomial relation; they are independent. There is a classical proof of these facts based on induction, using symmetrized monomials

\[
t_1^{a_1} t_2^{a_2} \cdots t_n^{a_n} + \text{all permutations thereof}
\]

and the lexicographic ordering of the list of exponents \(a_1, \ldots, a_n\) (see Exercise 8.2). A more modern but less constructive proof is given in Chapter 18.

Assuming that the \(s_j\) generate the fixed field, we consider the extension

\[
L : K = \mathbb{C}(t_1, \ldots, t_n) : \mathbb{C}(s_1, \ldots, s_n)
\]

We know that in \(L\) the polynomial \(F(t)\) in (8.3) factorizes completely as \(F(t) = (t - t_1) \cdots (t - t_n)\).

Since the \(s_j\) are independent indeterminates, \(F(t)\) is traditionally called the general polynomial of degree \(n\). The reason for this name is that this polynomial has a universal property: If we can solve \(F(t) = 0\) by radicals, then we can solve any specific complex
polynomial equation of degree \( n \) by radicals. Just substitute specific numbers for the coefficients \( s_j \). The converse, however, is not obvious. We might be able to solve every specific complex polynomial equation of degree \( n \) by radicals, but using a different formula each time. Then we would not be able to deduce a radical expression to solve \( F(t) = 0 \). So the adjective "general" is somewhat misleading; "generic" would be better, and is sometimes used.

The next definition is not standard, but its name is justified because it reflects the assumptions made by Ruffini in his attempted proof that the quintic is insoluble.

**DEFINITION 8.8** The general polynomial equation \( F(t) = 0 \) is soluble by Ruffini radicals if there exists a finite tower of subfields

\[
K = K_0 \subseteq K_1 \subseteq \cdots \subseteq K_r = L
\]

such that for \( j = 0, \ldots, r - 1 \),

\[
K_{j+1} = K_j(\alpha_j) \quad \text{and} \quad \alpha_j^{n_j} \in K_j \quad \text{for} \quad n_j \geq 2, \ n_j \in \mathbb{N}
\]

Ruffini tacitly assumed that if \( F(t) = 0 \) is soluble by radicals, then those radicals are all expressible as rational functions of the roots \( t_1, \ldots, t_n \). Indeed, this was the situation studied by his predecessor Lagrange in his deep but inconclusive research on the quintic. So Lagrange and Ruffini considered only solubility by Ruffini radicals. However, this is a strong assumption. It is entirely conceivable that a solution by radicals might exist for which the \( \alpha_j \) constructed along the way do not lie in \( L \), but in some extension of \( L \). For example, \( \sqrt[3]{5} \) might be useful. (It is useful to solve \( t^5 - 5 = 0 \), for instance, but the solutions of this equation do not belong to \( L \).)

However, the more we think about this possibility, the less likely it seems. Abel thought about it very hard and proved that if \( F(t) = 0 \) is soluble by radicals, then those radicals are all expressible as rational functions of the roots — they are Ruffini radicals after all. This step, historically called Abel's theorem, is more commonly referred to as the Theorem on Natural Irrationalities. From today's perspective, it is the main difficulty in the impossibility proof. So, following Lagrange and Ruffini, we start by defining the main difficulty away. As compensation, we gain excellent motivation for the remainder of this book.

For completeness, we prove the Theorem on Natural Irrationalities in Section 8.8 using classical (pre-Galois) methods. As preparation for all of the above, we need the following:

**PROPOSITION 8.9** If there is a finite tower of subfields (8.4), then it can be refined (if necessary increasing its length) to make all \( n_j \) prime.

**PROOF** For fixed \( j \), write \( n_j = p_1 \cdots p_k \) where the \( p_i \) are prime. Let \( \beta_j = \alpha_j^{p_1 \cdots p_i} \). Then \( \beta_j^{p_{i+1}} \in K_j(\alpha_j) \), and the rest is easy. \( \square \)
For the remainder of this chapter we assume that this refinement has been performed, and write \( p_j \) for \( n_j \) as a reminder. With this preliminary step completed, we will prove Theorem 8.10:

**Theorem 8.10**

The general polynomial equation \( F(t) = 0 \) is insoluble by Ruffini radicals if \( n \geq 5 \).

All we need is a simple group-theoretic lemma.

**Lemma 8.11**

1. The symmetric group \( S_n \) has a cyclic quotient group of prime order \( p \) if and only if \( p = 2 \) and \( n \geq 2 \), in which case the kernel is the alternating group \( A_n \).
2. The alternating group \( A_n \) has a cyclic quotient group of prime order \( p \) if and only if \( p = 3 \) and \( n = 3, 4 \).

**Proof**  
(1) We may assume \( n \geq 3 \) because there is nothing to prove when \( n = 1, 2 \). Suppose that \( N \) is a normal subgroup of \( S_n \) and \( S_n / N \cong \mathbb{Z}_p \). Then \( S_n / N \) is abelian, so \( N \) contains every commutator \( ghg^{-1}h^{-1} \) for \( g, h \in S_n \). To see why, let \( \bar{g} \) denote the image of \( g \in S_n \) in the quotient group \( S_n / N \). Since \( S_n / N \) is abelian, \( \bar{g} \bar{h} \bar{g}^{-1} \bar{h}^{-1} = \bar{1} \) in \( S_n / N \); that is, \( ghg^{-1}h^{-1} \in N \).

Let \( g, h \) be 2-cycles of the form \( g = (ab), h = (ac) \) where \( a, b, c \) are distinct. Then

\[
ghg^{-1}h^{-1} = (bca)
\]

is a 3-cycle, and all possible 3-cycles can be obtained in this way. Therefore, \( N \) contains all 3-cycles. But the 3-cycles generate \( A_n \), so \( N \subseteq A_n \). Therefore, \( p = 2 \) since \( |S_n / A_n| = 2 \).

(2) Suppose that \( N \) is a normal subgroup of \( A_n \) and \( A_n / N \cong \mathbb{Z}_p \). Again, \( N \) contains every commutator. If \( n = 2 \), then \( A_n \) is trivial. When \( n = 3 \) we know that \( A_n \cong \mathbb{Z}_3 \).

Suppose first that \( n = 4 \). Consider the commutator \( ghg^{-1}h^{-1} \) where \( g = (abc), h = (abd) \) for \( a, b, c, d \) distinct. Computation shows that

\[
ghg^{-1}h^{-1} = (ab)(cd)
\]

so \( N \) must contain \( (12)(34), (13)(24), \) and \( (14)(23) \). It also contains the identity. But these four elements form a group \( V \). Thus, \( V \subseteq N \). Since \( V \) is a normal subgroup of \( A_4 \) and \( A_4 / V \cong \mathbb{Z}_3 \), we are done.

The symbol \( V \) comes from Klein's term \( Vierergruppe \), or "fours-group." Nowadays it is usually called the \( Klein four-group \).

Finally, assume that \( n \geq 5 \). The same argument shows that \( N \) contains all permutations of the form \( (ab)(cd) \) if \( a, b, c, d, e \) are all distinct (which is why the case \( n = 4 \)
is special), then

\[(ab)(cd) \cdot (ab)(ce) = (ced)\]

so \(N\) contains all 3-cycles. But the 3-cycles generate \(A_n\), so this case cannot occur.

As our final preparatory step, we recall the expression

\[\delta = \prod_{j < k}^n (t_j - t_k)\]

It is not a symmetric polynomial in the \(t_j\), but its square \(\Delta = \delta^2\) is, because

\[\Delta = (-1)^{n(n-1)/2} \prod_{j \neq k}^n (t_j - t_k)\]

The expression \(\Delta\), mentioned in passing in Section 1.4, is called the discriminant of \(F(t)\). If \(\sigma \in S_n\), then the action of \(\sigma\) sends \(\delta\) to \(\pm \delta\). The even permutations (those in \(A_n\)) fix \(\delta\), and the odd ones map \(\delta\) to \(-\delta\). Indeed, this is a standard way to define odd and even permutations.

We are now ready for the proof.

**Proof of Theorem 18** Assume that \(F(t) = 0\) is soluble by Ruffini radicals, with a tower (8.4) of subfields \(K_j\) in which all \(n_j = p_j\) are prime. Consider the first step in the tower,

\[K \subseteq K_1 \subseteq L\]

where \(K_1 = K(\alpha_1), \alpha_1^p \in K, \alpha_1 \not\in K, \) and \(p = p_1\) is prime.

Since \(\alpha_1 \in L\) we can act on it by \(S_n\), and since every \(\sigma \in S_n\) fixes \(K\) we have

\[(\sigma(\alpha_1))^p = \alpha_1^p\]

Therefore, \(\sigma(\alpha_1) = \zeta^j(\alpha_1)\), for \(\zeta\) a primitive \(p\)th root of unity and \(j(\sigma)\) an integer between 0 and \(p - 1\). The set of all \(p\)th roots of unity in \(\mathbb{C}\) is a group under multiplication, and this group is cyclic, isomorphic to \(\mathbb{Z}_p\). Indeed, \(\zeta^a \cdot \zeta^b = \zeta^{a+b}\) where \(a + b\) is taken modulo \(p\).

Clearly, the map

\[j : S_n \rightarrow \mathbb{Z}_p\]

\[\sigma \mapsto j(\sigma)\]

is a group homomorphism. Since \(\alpha_1 \not\in K\), some \(\sigma(\alpha_1) \not\in K\), so \(j\) is nontrivial. Since \(\mathbb{Z}_p\) has prime order, hence no nontrivial proper subgroups, \(j\) must be onto. Therefore, \(S_n\) has a homomorphic image that is cyclic of order \(p\). By Lemma 11, \(p = 2\) and the kernel is \(A_n\). Therefore, \(\alpha_1\) is fixed by \(A_n\).
We claim that this implies that $\alpha_1 \in K(\delta)$. If $h(t_1, \ldots, t_n) \in L$ and $\sigma \in S_n$, we define $h^\sigma$ by

$$h^\sigma(t_1, \ldots, t_n) = h(t_{\sigma(1)}, \ldots, t_{\sigma(n)})$$

Suppose that $h$ is fixed by $A_n$, and let $\sigma = (12)$ be a transposition which lies in $S_n \setminus A_n$. Write $h = h_e + h_o$ where

$$h_e = \frac{1}{2}(h + h^\sigma), \quad h_o = \frac{1}{2}(h - h^\sigma)$$

Then $h_e$ is fixed by $A_n$ and $\sigma$, which generate $S_n$, so $h_e \in K$. Clearly, $h_o$ is mapped to $-h_o$ by $\sigma$ and fixed by $A_n$. Therefore, $\delta h_o$ is fixed by $\sigma$ and $A_n$, so is fixed by $S_n$, so $\delta h_o \in K$. Therefore, $h_o \in K(\delta)$. Finally, $h = h_e + h_o \in K + K(\delta) = K(\delta)$. Now apply this result with $h = \alpha_1$.

If $n = 2$ we are finished. Otherwise consider the second step in the tower

$$K(\delta) \subseteq K_2 = K(\delta)(\alpha_2)$$

By a similar argument, $\alpha_2$ defines a group homomorphism $j : A_n \to \mathbb{Z}_p$, which again must be onto. By Lemma 11, $p = 3$ and $n = 3, 4$. In particular, no tower of Ruffini radicals exists when $n \geq 5$.

It is plausible that any tower of radicals that leads from $K$ to a subfield containing $L$ must give rise to a tower of Ruffini radicals. However, it is not at all clear how to prove this and, in fact, this is where the main difficulty of the problem really lies, once the role of permutations is understood. Ruffini appeared not to notice that this needed proof. Abel tackled the obstacle head on. Galois worked his way round it by way of the Galois group — an extremely elegant solution.

His method also went much further; it applies not just to the general polynomial $F(t)$, but to any polynomial whatsoever. And it provides necessary and sufficient conditions for solutions by radicals to exist.

Exercises 8.8 to 8.10 provide enough hints for you to show that when $n = 2, 3, 4$ the equation $\phi(t) = 0$ can be solved by Ruffini radicals. Therefore, despite the special nature of Ruffini radicals, we see that the quintic equation differs (radically) from the quadratic, cubic, and quartic equations. We also appreciate the significant role of group theory and symmetries of the roots of a polynomial for the existence, or not, of a solution by radicals. This will serve us in good stead when the going gets tougher.

---

### 8.8 Natural Irrationalities

With a little more effort we can go the whole hog. Abel's proof contains one further idea that lets us delete the word Ruffini from Theorem 8.10. This section is an optional extra, and nothing later depends on it. We continue to work with the general
polynomial, so throughout this section \( L = \mathbb{C}(t_1, \ldots, t_n) \) and \( K = \mathbb{C}(s_1, \ldots, s_n) \), where the \( s_j \) are the elementary symmetric polynomials in the \( t_j \). The essential point is Theorem 8.12.

**THEOREM 8.12**
If the general polynomial equation \( F(t) = 0 \) can be solved by radicals, then it can be solved by Ruffini radicals.

**COROLLARY 8.13**
The general polynomial equation \( F(t) = 0 \) is insoluble by radicals if \( n \geq 5 \).

To prove the above, all we need is the so-called Theorem on Natural Irrationalities, which states that extraneous radicals like \( \sqrt[3]{5} \) cannot help in the solution of \( F(t) = 0 \). More precisely;

**THEOREM 8.14 (Natural Irrationalities)**
If \( L \) contains an element \( x \) that lies in some radical extension \( R \) of \( K \), then there exists a radical extension \( R' \) of \( K \) with \( x \in R' \) and \( R' \subseteq L \).

Once we have proved Theorem 8.14, any solution of \( F(t) = 0 \) by radicals can be converted into one by Ruffini radicals. Theorem 8.12 and Corollary 8.13 are then immediate.

It remains to prove Theorem 8.14. A proof using Galois theory is straightforward (see Exercise 15.14). With what we know at the moment, we have to work a little harder — but, following Abel’s strategic insights, not much harder. We need several lemmas and a technical definition.

**DEFINITION 8.15**
Let \( R : K \) be a radical extension. The height of \( R : K \) is the smallest integer \( h \) such that there exist elements \( \alpha_1, \ldots, \alpha_h \in R \) and primes \( p_1, \ldots, p_h \) such that \( R = K(\alpha_1, \ldots, \alpha_h) \) and

\[ \alpha_j^{p_j} \in K(\alpha_1, \ldots, \alpha_{j-1}) \quad 1 \leq j \leq h \]

where when \( j = 1 \) we interpret \( K(\alpha_1, \ldots, \alpha_{j-1}) \) as \( K \).

Proposition 8.9 shows that every radical extension has finite height.

We prove Theorem 8.14 by induction on the height of a radical extension \( R \) that contains \( v \). The key step is extensions of height 1, and this is where all the work is put in.

**LEMMA 8.16**
Let \( M \) be a subfield of \( L \) such that \( K \subseteq M \), and let \( a \in M \), where \( a \) is not a \( p \)th power in \( M \). Then

1. \( a^k \) is not a \( p \)th power in \( M \) for \( k = 1, 2, \ldots, p \).

2. The polynomial \( m(t) = t^p - a \) is irreducible over \( M \).
PROOF
(1) Since \( k \) is prime to \( p \) there exist integers \( q, l \) such that \( kp + ql = 1 \). If \( a^k = b^p \) with \( b \in M \), then

\[
(a^q b^l)^p = a^{qp} b^{lp} = a^{qp} a^{kl} = a
\]

contrary to \( a \) not being a \( p \)th power in \( M \).

(2) It would be easy to prove that \( t^p - a \) is irreducible if we could write it as a product of linear factors, but that option is not open to us at this stage in the book. The proof is, therefore, less direct.

Suppose that \( P(t) \) is a monic irreducible factor of \( m(t) = t^p - a \) over \( M \). For \( 0 \leq j \leq p - 1 \) let \( P_j(t) = P(\zeta^j t) \), where \( \zeta \in \mathbb{C} \subseteq K \subseteq M \) is a primitive \( p \)th root of unity. Then \( P_0 = P \), and \( P_j \) is irreducible for all \( j \), for if \( P(\zeta^j t) = g(t)h(t) \) then \( P(t) = g(\zeta^{-j} t)h(\zeta^{-j} t) \). Moreover, \( m(\zeta^j t) = (\zeta^j t)^p - a = t^p - a = m(t) \), so \( P_j \) divides \( m \) for all \( j = 0, \ldots, p - 1 \) by Lemma 5.6.

We claim that \( P \) and \( P_j \) are coprime whenever \( 0 \leq j < k \leq p - 1 \). If not, by irreducibility

\[
P_j(t) = cP(t) \quad c \in M
\]

Let

\[
P(t) = p_0 + p_1 t + \cdots + p_{r-1} t^{r-1} + t^r
\]

where \( r \leq p \). By irreducibility, \( p_0 \neq 0 \). Then

\[
P_j(t) = p_0 + p_1 \zeta^j t + \cdots + p_{r-1} \zeta^{j(r-1)} t^{r-1} + \zeta^j t^r
\]

\[
P_k(t) = p_0 + p_1 \zeta^k t + \cdots + p_{r-1} \zeta^{k(r-1)} t^{r-1} + \zeta^k t^r
\]

so \( c = \zeta^{(j-k)r} \) from the coefficient of \( t^r \). But then \( p_0 = \zeta^{(j-k)r} p_0 \). Since \( p_0 \neq 0 \), we must have \( \zeta^{(j-k)r} = 1 \), so \( r = p \). But this implies that \( \partial p = \partial m \), so \( m \) is irreducible over \( M \).

Thus we may assume that the \( P_j \) are pairwise coprime. We know that \( P_j \mid m \) for all \( j \), so

\[
P_0 P_1 \ldots P_{p-1} \mid m
\]

When \( \partial p = r \), it follows that \( pr \leq p \), so \( r = 1 \). Thus \( P \) is linear, so there exists \( b \in M \) such that \( (t - b) \mid m(t) \). But this implies that \( b^p = a \), contradicting the assumption that \( a \) is not a \( p \)th root. Thus \( t^p - a \) is irreducible. \( \square \)

Now suppose that \( R \) is a radical extension of height 1 over \( M \). Then \( R = M(\alpha) \) where \( \alpha^p \in M \), \( \alpha \not\in M \).

(To avoid cheating you here, we must explain what is meant by \( M(\alpha) \) when \( \alpha \not\in L \). We mean \( M[t] \) modulo the polynomial \( m \). As in Section 5.3, all the usual laws of algebra hold for \( M[t] \) modulo \( m \), because \( m \) is irreducible. If we had developed
everything for general fields instead of subfields of \( \mathbb{C}(t_1, \ldots, t_n) \), the explanation would not be required. There is a price to pay for staying concrete.)

Therefore, every \( x \in R \setminus M \) is uniquely expressible as

\[
x = x_0 + x_1 \alpha + x_2 \alpha^2 + \cdots + x_{p-1} \alpha^{p-1}
\]

where the \( x_j \in M \). This follows since \([M(\alpha) : M] = p\) by irreducibility of \( M \). We want to put \( x \) into a more convenient form by changing \( \alpha \) to some other element \( \beta \) of \( M(\alpha) \) and, therefore, changing \( a \) to \( b = \beta^p \). In this new form, \( x_1 = 1 \). The precise statement is:

**Lemma 8.17**

For a given \( x \in R \), there exist \( \beta \in M(\alpha) \) and \( b \in M \) with \( b = \beta^p \), such that \( b \) is not the \( p \)th power of an element of \( M \), and

\[
x = y_0 + \beta + y_2 \beta^2 + \cdots + y_{p-1} \beta^{p-1}
\]

where the \( y_j \in M \).

**Proof** We know that \( x \notin M \), so in (8.5) some \( x_s \neq 0 \) for \( 1 \leq s \leq p - 1 \). Let \( \beta = x_s \alpha^s \), and let \( b = \beta^p \). Then \( b = x_s^p \alpha^{sp} = x_s^p a^s \), and if \( b \) is a \( p \)th power of an element of \( M \) then \( a^s \) is a \( p \)th power of an element of \( M \), contrary to Lemma 8.16(2). Therefore, \( b \) is not the \( p \)th power of an element of \( M \).

Now \( s \) is prime to \( p \), and the additive group \( \mathbb{Z}_p \) is cyclic of prime order \( p \), so \( s \) generates \( \mathbb{Z}_p \). Therefore, the powers \( \beta^j \) of \( \beta \) run through the powers of \( \alpha \) precisely once as \( j \) runs from 0 to \( p - 1 \). Since \( \beta^0 = 1 \), \( \beta^1 = \alpha^s \), we have

\[
x = y_0 + \beta + y_2 \beta^2 + \cdots + y_{p-1} \beta^{p-1}
\]

for suitable \( y_j \in M \), where in fact \( y_0 = x_0 \). \( \Box \)

**Lemma 8.18**

Let \( q \in L \). Then the minimal polynomial of \( q \) over \( K \) splits into linear factors over \( L \).

**Proof** The element \( q \) is a rational expression \( q(t_1, \ldots, t_n) \in \mathbb{C}(t_1, \ldots, t_n) \). The polynomial

\[
f_q(t) = \prod_{\sigma \in S} (t - q(t_{\sigma(1)}, \ldots, t_{\sigma(n)}))
\]

has \( q \) as a zero. Symmetry under \( S_n \) implies that \( f_q(t) \in K[t] \). The minimal polynomial \( m_q \) of \( q \) over \( K \) divides \( f_q \), and \( f_q \) is a product of linear factors; therefore, \( m_q \) is the product of some subset of those linear factors. \( \Box \)

We are now ready for the climax of Diet Galois.
PROOF OF THEOREM 8.14 We prove the theorem by induction on the height \( h \) of \( R \).

If \( h = 0 \), then the theorem is obvious.

Suppose that \( h \geq 1 \). Then \( R = R_1(\alpha) \) where \( R_1 \) is a radical extension of \( K \) of height \( h - 1 \), and \( \alpha^p \in R_1 \), \( \alpha \not\in R_1 \), with \( p \) prime. Let \( \alpha^p = a \in R_1 \).

By Lemma 8.17 we may assume without loss of generality that

\[
x = x_0 + \alpha + x_2\alpha^2 + \cdots + \alpha^{p-1}x_{p-1}
\]

where the \( x_j \in R_1 \). (Replace \( \alpha \) by \( \beta \) as in the lemma, and then change notation back to \( \alpha \).) The minimum polynomial \( m(t) \) of \( x \) over \( K \) splits into linear factors in \( L \) by Lemma 8.18. In particular, \( x \) is a zero of \( m(t) \), while all zeros of \( m(t) \) lie in \( L \). Therefore, \( \alpha, x_0, x_2, \ldots x_{p-1} \in L \).

Also, \( \alpha, x_0, x_2, \ldots x_{p-1} \in R_1 \). The height of \( R_1 \) is \( h - 1 \), so by induction, each of these elements lies in some radical extension of \( K \) that is contained in \( L \). The subfield \( J \) generated by all of these elements is clearly radical (Exercise 8.6), and contains \( \alpha^p, x_0, x_2, \ldots x_{p-1} \). Then \( x \in J(\alpha) \subseteq L \), and \( J(\alpha) \) is radical. This completes the induction step, and with it, the proof.

So much for the general quintic. We have used virtually everything that led up to Galois theory, but instead of thinking of a group of automorphisms of a field extension, we have used a group of permutations of the roots of a polynomial. Indeed, we have used only the group \( S_n \), which permutes the roots \( t_j \) of the general polynomial \( F(t) \). It would be possible to stop here, with a splendid application of group theory to the insolubility of the general quintic. But for Galois, and for us, there is much more to do. The general quintic is not general enough, and it would be nice to find out why the various tricks used above actually work. At the moment, they seem to be fortunate accidents. In fact, they conceal an elegant theory (which, in particular, makes the Theorem on Natural Irrationalities entirely obvious; so much so that we can ignore it altogether). That theory is, of course, Galois theory. Motivated up the the hilt, we can start to develop it in earnest.

---

**Exercises**

8.1 Show that the only subfields of \( \mathbb{Q}(i, \sqrt{5}) \) are \( \mathbb{Q}, \mathbb{Q}(i), \mathbb{Q}(\sqrt{5}), \mathbb{Q}(i\sqrt{5}) \), and \( \mathbb{Q}(i, \sqrt{5}) \).

8.2 Express the following in terms of elementary symmetric polynomials of \( \alpha, \beta, \gamma \).

a. \( \alpha^2 + \beta^2 + \gamma^2 \)
b. \( \alpha^2 \beta + \alpha^2 \gamma + \beta^2 \alpha + \beta^2 \gamma + \gamma^2 \alpha + \gamma^2 \beta \)
c. \( \alpha^3 + \beta^3 + \gamma^3 \)
d. \( (\alpha - \beta)^2 + (\beta - \gamma)^2 + (\gamma - \alpha)^2 \)
8.3 Prove that every symmetric polynomial \( p(x, y) \in \mathbb{Q}[x, y] \) can be written as a polynomial in \( xy \) and \( x + y \) as follows. If \( p \) contains a term \( ax^iy^j \), with \( i \neq j \in \mathbb{N} \) and \( a \in \mathbb{Q} \), show that it must also contain the term \( ax^jy^i \). Use this to write \( p \) as a sum of terms of the form \( a(x^iy^j + x^jy^i) \) or \( ax^jy^i \). Observe that

\[
x^iy^j + x^jy^i = x^iy^j(x^{j-i} + y^{j-i}) \quad \text{if} \quad i < j
\]

\[
x^i y^j = (xy)^j
\]

\[
(x^i + y^j) = (x + y)(x^{i-1} + y^{j-1}) - xy(x^{i-2} + y^{j-2}).
\]

Hence show that \( p \) is a sum of terms that are polynomials in \( x + y, xy \).

8.4* This exercise generalizes Exercise 2.12 to \( n \) variables. Suppose that \( p(t_1, \ldots, t_n) \in K[t_1, \ldots, t_n] \) is symmetric and let the \( s_i \) be the elementary symmetric polynomials in the \( t_j \). Define the rank of a monomial \( t_1^{a_1}t_2^{a_2} \cdots t_n^{a_n} \) to be \( a_1 + 2a_2 + \cdots + na_n \). Define the rank of \( p \) to be the maximum of the ranks of all monomials that occur in \( p \), and let its part of highest rank be the sum of the terms whose ranks attain this maximum value. Find a polynomial \( q \) composed of terms of the form \( k\delta_1^{a_1}\delta_2^{a_2} \cdots \delta_n^{a_n} \), where \( k \in K \), such that the part of \( q \) of highest rank equals that of \( p \). Observe that \( p - q \) has smaller rank than \( p \), and use induction on the rank to prove that \( p \) is a polynomial in the \( s_i \).

8.5 Suppose that \( f(t) = a_n t^n + \cdots + a_0 \in K[t] \), and suppose that in some subfield \( L \) of \( \mathbb{C} \) such that \( K \subset L \) we can factorize \( f \) as

\[
f(t) = a_n (t - \alpha_1) \cdots (t - \alpha_n)
\]

Define

\[
\lambda_j = \alpha_1^j + \cdots + \alpha_n^j
\]

Prove Newton's identities

\[
a_{n-1} + a_n \lambda_1 = 0
\]

\[
2a_{n-2} + a_{n-1} \lambda_1 + a_n \lambda_2 = 0
\]

\[
\cdots
\]

\[
na_0 + a_1 \lambda_1 + \cdots + a_{n-1} \lambda_{n-1} + a_n \lambda_n = 0
\]

\[
\cdots
\]

\[
a_0 \lambda_k + a_1 \lambda_{k+1} + \cdots + a_{n-1} \lambda_{k+n-1} + a_n \lambda_{k+1}n = 0 \quad (k \geq 1)
\]

Show how to use these identities inductively to obtain formulas for the \( \lambda_j \).

8.6 Prove that the alternating group \( A_n \) is generated by 3-cycles.

8.7 Prove that every element of \( A_5 \) is the product of two 5-cycles. Deduce that \( A_5 \) is simple.
8.8 Solve the general quadratic by Ruffini radicals. (*Hint:* If the roots are \( \alpha_1, \alpha_2 \), show that \((\alpha_1 - \alpha_2)^2\) is a Ruffini radical.)

8.9 Solve the general cubic by Ruffini radicals. (*Hint:* If the roots are \( \alpha_1, \alpha_2, \alpha_3 \), show that \( \alpha_1 + \omega \alpha_2 + \omega^2 \alpha_3 \) and \( \alpha_1 + \omega^2 \alpha_2 + \omega \alpha_3 \) are Ruffini radicals.)

8.10 Solve the general quartic by Ruffini radicals. (*Hint:* If the roots are \( \alpha_1, \alpha_2, \alpha_3, \alpha_4 \), show that \( \alpha_1 + i^k \alpha_2 + i^{2k} \alpha_3 + i^{3k} \alpha_4 \) is a Ruffini radical for \( 0 \leq k \leq 3 \).

8.11 Suppose that \( I \subseteq J \) are subfields of \( \mathbb{C}(t_1, \ldots, t_n) \) (that is, subsets closed under the operations \(+, -, \times, \div\)), and \( J \) is generated by \( J_1, \ldots, J_r \), where \( I \subseteq J_j \subseteq J \) for each \( j \) and \( J_j : I \) is radical. By induction on \( r \), prove that \( J : I \) is radical.

8.12 Mark the following true or false.

a. The \( K \)-automorphisms of a field extension \( L : K \) form a subfield of \( \mathbb{C} \).

b. The \( K \)-automorphisms of a field extension \( L : K \) form a group.

c. The fixed field of the Galois group of \( L : K \) contains \( K \).

d. The fixed field of the Galois group of \( L : K \) equals \( K \).

e. The alternating group \( A_5 \) has a normal subgroup \( H \) with quotient isomorphic to \( \mathbb{Z}_5 \).

f. The alternating group \( A_5 \) has a normal subgroup \( H \) with quotient isomorphic to \( \mathbb{Z}_3 \).

g. The alternating group \( A_5 \) has a normal subgroup \( H \) with quotient isomorphic to \( \mathbb{Z}_2 \).

h. The general quintic equation can be solved using radicals, but it cannot be solved using Ruffini radicals.
Chapter 9

Normality and Separability

In this chapter we define the important concepts of normality and separability and develop some key properties.

Suppose that $K$ is a subfield of $\mathbb{C}$. Often a polynomial $p(t) \in K[t]$ has no zeros in $K$. But it must have zeros in $\mathbb{C}$, by the Fundamental Theorem of Algebra. Therefore, it may have some zeros, at least, in some given extension field $L$ of $K$. For example, $i^2 + 1 \in \mathbb{R}[t]$ has no zeros in $\mathbb{R}$, but has zeros $\pm i \in \mathbb{C}$. We shall study this phenomenon in detail, showing that every polynomial can be resolved into a product of linear factors (and hence has its full complement of zeros) if the ground field $K$ is extended to a suitable splitting field $N$. An extension $N : K$ is normal if any irreducible polynomial over $K$ with at least one zero in $N$ splits into linear factors in $N$. We show that an extension is normal if and only if it is a splitting field.

Separability is a complementary property to normality. An irreducible polynomial is separable if its zeros in its splitting field are simple. It turns out that over $\mathbb{C}$ this property is automatic. We make it explicit because it is not automatic for more general fields, see Chapter 16.

9.1 Splitting Fields

The most tractable polynomials are products of linear ones, so we are led to single this property out.

**Definition 9.1** If $K$ is a subfield of $\mathbb{C}$ and $f$ is a polynomial over $K$, then $f$ splits over $K$ if it can be expressed as a product of linear factors

$$f(t) = k(t - \alpha_1) \cdots (t - \alpha_n)$$

where $k, \alpha_1, \ldots, \alpha_n \in K$.

If this is the case, then the zeros of $f$ in $K$ are precisely $\alpha_1, \ldots, \alpha_n$. The Fundamental Theorem of Algebra implies that $f$ splits over $K$ if and only if all of its zeros in $\mathbb{C}$ actually lie in $K$. Equivalently, $K$ contains the subfield generated by all the zeros of $f$. 
Example 9.2

1. The polynomial \( f(t) = t^3 - 1 \in \mathbb{Q}[t] \) splits over \( \mathbb{C} \), because it can be written as
\[
f(t) = (t - 1)(t - \omega)(t - \omega^2)
\]
where \( \omega = \exp(2\pi i / 3) \in \mathbb{C} \). Similarly, \( f \) splits over the subfield \( \mathbb{Q}(i, \sqrt{3}) \) since \( \omega \in \mathbb{Q}(i, \sqrt{3}) \), and indeed \( f \) splits over \( \mathbb{Q}(\omega) \), the smallest subfield of \( \mathbb{C} \) with that property.

2. The polynomial \( f(t) = t^4 - 4t^2 - 5 \) splits over \( \mathbb{Q}(i, \sqrt{5}) \), because
\[
f(t) = (t - i)(t + i)(t - \sqrt{5})(t + \sqrt{5})
\]
However, over \( \mathbb{Q}(i) \) the best we can do is factorize it as
\[
(t - i)(t + i)(t^2 - 5)
\]
with an irreducible factor \( t^2 - 5 \) of degree greater than 1. (It is easy to show that 5 is not a square in \( \mathbb{Q}(i) \).)

So over \( \mathbb{Q}(i) \), the polynomial \( f \) does not split. This shows that even if a polynomial \( f(t) \) has some linear factors in an extension field \( L \), it need not split over \( L \).

If \( f \) is a polynomial over \( K \) and \( L \) is an extension field of \( K \), then \( f \) is also a polynomial over \( L \). It therefore makes sense to talk of \( f \) splitting over \( L \), meaning that it is a product of linear factors with coefficients in \( L \). We show that given \( K \) and \( f \) we can always construct an extension \( \Sigma \) of \( K \) such that \( f \) splits over \( \Sigma \). It is convenient to require in addition that \( f \) does not split over any smaller field, so that \( \Sigma \) is as economical as possible.

**Definition 9.3** A subfield \( \Sigma \) of \( \mathbb{C} \) is a splitting field for the polynomial \( f \) over the subfield \( K \) of \( \mathbb{C} \) if \( K \subseteq \Sigma \) and

1. \( f \) splits over \( \Sigma \).
2. If \( K \subseteq \Sigma' \subseteq \Sigma \) and \( f \) splits over \( \Sigma' \), then \( \Sigma' = \Sigma \).

The second condition is clearly equivalent to:

2'. \( \Sigma = K(\sigma_1, \ldots, \sigma_n) \) where \( \sigma_1, \ldots, \sigma_n \) are the zeros of \( f \) in \( \Sigma \).

Clearly, every polynomial over a subfield \( K \) of \( \mathbb{C} \) has a splitting field.

**Theorem 9.4**

If \( K \) is any subfield of \( \mathbb{C} \) and \( f \) is any polynomial over \( K \), then there exists a unique splitting field \( \Sigma \) for \( f \) over \( K \). Moreover, \( [\Sigma : K] \) is finite.
9.1 Splitting Fields

PROOF We can take $\Sigma = K(\sigma_1, \ldots, \sigma_n)$, where the $\sigma_j$ are the zeros of $f$ in $\mathbb{C}$. In fact, this is the only possibility, so $\Sigma$ is unique. The degree $[\Sigma : K]$ is finite since $K(\sigma_1, \ldots, \sigma_n)$ is finitely generated and algebraic, so Lemma 6.11 applies.

Isomorphic subfields of $\mathbb{C}$ have isomorphic splitting fields, in the following strong sense.

**LEMMA 9.5**
Suppose that $\iota : K \rightarrow K'$ is an isomorphism of subfields of $\mathbb{C}$. Let $f$ be a polynomial over $K$ and let $\Sigma \supseteq K$ be the splitting field for $f$. Let $L$ be any extension field of $K'$ such that $\iota(f)$ splits over $L$. Then there exists a monomorphism $j : \Sigma \rightarrow L$ such that $j|_K = \iota$.

PROOF We have the following situation:

$$
\begin{array}{ccc}
K & \rightarrow & \Sigma \\
\iota \downarrow & \downarrow j \\
K' & \rightarrow & L
\end{array}
$$

where $j$ has yet to be found. We construct $j$ using induction on $\partial f$. As a polynomial over $\Sigma$,

$$f(t) = k(t - \sigma_1) \cdots (t - \sigma_n)$$

The minimal polynomial $m$ of $\sigma_1$ over $K$ is an irreducible factor of $f$. Now $\iota(m)$ divides $\iota(f)$ which splits over $L$, so that over $L$

$$\iota(m) = (t - \alpha_1) \cdots (t - \alpha_r)$$

where $\alpha_1, \ldots, \alpha_r \in L$. Since $\iota(m)$ is irreducible over $K'$, it must be the minimal polynomial of $\alpha_1$ over $K'$. So by Theorem 16 there is an isomorphism

$$j_1 : K(\alpha_1) \rightarrow K'(\alpha_1)$$

such that $j_1|_K = \iota$ and $j_1(\sigma_1) = \alpha_1$. Now $\Sigma$ is a splitting field over $K(\sigma_1)$ of the polynomial $g = f/(t - \sigma_1)$. By induction there exists a monomorphism $j : \Sigma \rightarrow L$ such that $j|_{K(\sigma_1)} = j_1$. But then $j|_K = \iota$ and we are finished.

This enables us to prove the uniqueness theorem.

**THEOREM 9.6**
Let $\iota : K \rightarrow K'$ be an isomorphism. Let $\Sigma$ be the splitting field for $f$ over $K$, and let $\Sigma'$ be the splitting field for $\iota(f)$ over $K'$. Then there is an isomorphism $j : \Sigma \rightarrow \Sigma'$ such that $j|_K = \iota$. In other words, the extensions $\Sigma : K$ and $\Sigma' : K'$ are isomorphic.
PROOF We start with the following diagram:

\[
\begin{array}{c}
K \to \Sigma \\
j \downarrow \downarrow j \\
K' \to \Sigma'
\end{array}
\]

We must find \( j \) to make the diagram commute, given the rest of the diagram. By Lemma 9.5 there is a monomorphism \( j : \Sigma \to \Sigma' \) such that \( j|_K = \iota \). But \( j(\Sigma) \) is clearly the splitting field for \( \iota(f) \) over \( K' \), and is contained in \( \Sigma' \). Since \( \Sigma' \) is also the splitting field for \( \iota(f) \) over \( K' \), we have \( j(\Sigma) = \Sigma' \), so that \( j \) is onto. Hence \( j \) is an isomorphism, and the theorem follows.

\[ \square \]

Example 9.7

1. Let \( f(t) = (t^2 - 3)(t^3 + 1) \) over \( \mathbb{Q} \). We can construct a splitting field for \( f \) as follows: over \( \mathbb{C} \) the polynomial \( f \) splits into linear factors

\[
f(t) = (t + \sqrt{3})(t - \sqrt{3})(t + 1) \left( t - \frac{1 + i\sqrt{3}}{2} \right) \left( t - \frac{1 - i\sqrt{3}}{2} \right)
\]

so there exists a splitting field in \( \mathbb{C} \), namely,

\[
\mathbb{Q}\left(\sqrt{3}, \frac{1 + i\sqrt{3}}{2}\right)
\]

This is clearly the same as \( \mathbb{Q}(\sqrt{3}, i) \).

2. Let \( f(t) = (t^2 - 2t - 2)(t^2 + 1) \) over \( \mathbb{Q} \). The zeros of \( f \) in \( \mathbb{C} \) are \( 1 \pm \sqrt{3}, \pm i \), so a splitting field is afforded by \( \mathbb{Q}(1 + \sqrt{3}, i) \) which equals \( \mathbb{Q}(\sqrt{3}, i) \). This is the same field as in the previous example, although the two polynomials involved are different.

3. It is even possible to have two distinct irreducible polynomials with the same splitting field. For example, \( t^2 - 3 \) and \( t^2 - 2t - 2 \) are both irreducible over \( \mathbb{Q} \), and both have \( \mathbb{Q}(\sqrt{3}) \) as their splitting field over \( \mathbb{Q} \).

\[ \]

9.2 Normality

The idea of a normal extension was explicitly recognized by Galois (but, as always, in terms of polynomials over \( \mathbb{C} \)). In the modern treatment it takes the following form.

**Definition 9.8** A field extension \( L : K \) is normal if every irreducible polynomial \( f \) over \( K \) that has at least one zero in \( L \) splits in \( L \).
9.2 Normality

For example, \( \mathbb{C} : \mathbb{R} \) is normal since every polynomial (irreducible or not) splits in \( \mathbb{C} \). On the other hand, we can find extensions that are not normal. Let \( \alpha \) be the real cube root of 2 and consider \( \mathbb{Q}(\alpha) : \mathbb{Q} \). The irreducible polynomial \( r^3 - 2 \) has a zero, namely, \( \alpha \), in \( \mathbb{Q}(\alpha) \), but it does not split in \( \mathbb{Q}(\alpha) \). If it did, then there would be three real cube roots of 2, not all equal. This is absurd.

Compare with the examples of Galois groups given in Chapter 8. The normal extension \( \mathbb{C} : \mathbb{R} \) has a well-behaved Galois group, in the sense that the Galois correspondence is a bijection. The same goes for \( \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5}) : \mathbb{Q} \). In contrast, the non-normal extension \( \mathbb{Q}(\alpha) : \mathbb{Q} \) has a badly behaved Galois group. Although this is not the whole story, it illustrates the importance of normality.

There is a close connection between normal extensions and splitting fields which provides a wide range of normal extensions.

**THEOREM 9.9**

A field extension \( L : K \) is normal and finite if and only if \( L \) is a splitting field for some polynomial over \( K \).

**PROOF** Suppose \( L : K \) is normal and finite. By Lemma 6.11, \( L = K(\alpha_1, \ldots, \alpha_s) \) for certain \( \alpha_j \) algebraic over \( K \). Let \( m_j \) be the minimal polynomial of \( \alpha_j \) over \( K \) and let \( f = m_1 \cdots m_s \). Each \( m_j \) is irreducible over \( K \) and has a zero \( \alpha_j \in L \), so by normality each \( m_j \) splits over \( L \). Hence \( f \) splits over \( L \). Since \( L \) is generated by \( K \) and the zeros of \( f \), it is the splitting field for \( f \) over \( K \). \( \Box \)

To prove the converse, suppose that \( L \) is the splitting field for some polynomial \( g \) over \( K \). The extension \( L : K \) is then obviously finite; we must show it is normal. To do this we must take an irreducible polynomial \( f \) over \( K \) with a zero in \( L \) and show that it splits in \( L \). Let \( M \supseteq L \) be a splitting field for \( fg \) over \( K \). Suppose that \( \theta_1 \) and \( \theta_2 \) are zeros of \( f \) in \( M \). By irreducibility, \( f \) is the minimal polynomial of \( \theta_1 \) and \( \theta_2 \) over \( K \).

We claim that

\[
[L(\theta_1) : L] = [L(\theta_2) : L]
\]

This is proved by an interesting trick. We look at several subfields of \( M \), namely, \( K, L, K(\theta_1), L(\theta_1), K(\theta_2), L(\theta_2) \). There are two towers

\[
K \subseteq K(\theta_1) \subseteq L(\theta_1) \subseteq M
\]

\[
K \subseteq K(\theta_2) \subseteq L(\theta_2) \subseteq M
\]

Furthermore, \( K \subseteq K(\theta_1) \) and \( L \subseteq L(\theta_j) \) for \( j = 1, 2 \), and \( K \subseteq L \subseteq M \). The claim will follow from a simple computation of degrees. For \( j = 1 \) or 2,

\[
[L(\theta_j) : L][L : K] = [L(\theta_j) : K] = [L(\theta_j) : K(\theta_j)][K(\theta_j) : K]
\]

(9.1)

By Proposition 6.7, \([K(\theta_1) : K] = [K(\theta_2) : K]\). Clearly, \( L(\theta_j) \) is the splitting field for \( g \) over \( K(\theta_j) \), and by Corollary 5.13 \( K(\theta_1) \) is isomorphic to \( K(\theta_2) \). Therefore, by
Theorem 9.6 the extensions $L(\theta_j) : K(\theta_j)$ are isomorphic for $j = 1, 2$, and hence have the same degree. Substituting in (8.1) and cancelling,

$$[L(\theta_1) : L] = [L(\theta_2) : L]$$

as claimed. From this point on, the rest is easy. If $\theta_1 \in L$, then $[L(\theta_1) : L] = 1$, so $[L(\theta_2) : L] = 1$ and $\theta_2 \in L$ also. Hence $L : K$ is normal.

---

### 9.3 Separability

Galois did not explicitly recognize the concept of separability, because he worked only with the complex field, where, as we shall see, separability is automatic. However, the concept is implicit in several of his proofs, and must be invoked when studying more general fields.

**DEFINITION 9.10** An irreducible polynomial $f$ over a subfield $K$ of $\mathbb{C}$ is separable over $K$ if it has simple zeros in $\mathbb{C}$, or equivalently, simple zeros in its splitting field.

This means that over its splitting field, or over $\mathbb{C}$, $f$ takes the form

$$f(t) = k(t - \sigma_1) \cdots (t - \sigma_n)$$

where the $\sigma_j$ are all different.

**Example 9.11**

The polynomial $t^4 + t^3 + t^2 + t + 1$ is separable over $\mathbb{Q}$, for its zeros in $\mathbb{C}$ are $\exp(2\pi i/5)$, $\exp(4\pi i/5)$, $\exp(6\pi i/5)$, $\exp(8\pi i/5)$, which are all different.

For polynomials over $\mathbb{R}$ there is a standard method for detecting multiple zeros by differentiation. To obtain maximum generality later, we redefine the derivative in a purely formal manner.

**DEFINITION 9.12** Suppose that $K$ is a subfield of $\mathbb{C}$, and let

$$f(t) = a_0 + a_1 t + \cdots + a_n t^n \in K[t]$$

Then the formal derivative of $f$ is the polynomial

$$Df = a_1 + 2a_2 t + \cdots + na_n t^{n-1} \in K[t]$$

For $K = \mathbb{R}$ (and indeed for $K = \mathbb{C}$) this is the usual derivative. There is in general no point in trying to think of $Df$ as a rate of change of $f$, but certain of the more
useful properties of the derivative carry over to $D$. In particular, simple computations (Exercise 9.3) show that for all polynomials $f$ and $g$ over $K$,

$$D(f + g) = Df + Dg$$

$$D(fg) = (Df)g + f(Dg)$$

Also, if $\lambda \in K$ then $D(\lambda) = \lambda$, so

$$D(\lambda f) = \lambda(Df)$$

These properties of $D$ let us state a criterion for the existence of multiple zeros without knowing what the zeros are.

**LEMMA 9.13**

Let $f \neq 0$ be a polynomial over a subfield $K$ of $C$, and let $\Sigma$ be its splitting field. Then $f$ has a multiple zero (in $C$ or $\Sigma$) if and only if $f$ and $Df$ have a common factor of degree $\geq 1$ in $\Sigma[t]$.

**PROOF** Suppose $f$ has a repeated zero in $\Sigma$, so that over $\Sigma$

$$f(t) = (t - \alpha)^2 g(t)$$

where $\alpha \in \Sigma$. Then

$$Df = (t - \alpha)[(t - \alpha)Dg + 2g]$$

so $f$ and $Df$ have a common factor $(t - \alpha)$ in $\Sigma[t]$. Hence $f$ and $Df$ have a common factor in $K[t]$, namely, the minimal polynomial of $\alpha$ over $K$.

Now suppose that $f$ has no repeated zeros. We show by induction on $\deg f$ that $f$ and $Df$ are coprime in $\Sigma[t]$, hence also coprime in $K[t]$. If $\deg f = 1$, this is obvious. Otherwise $f(t) = (t - \alpha)g(t)$ where $(t - \alpha) \mid g(t)$. Then

$$Df = (t - \alpha)Dg + g$$

If an irreducible factor of $g$ divides $Df$, then it must also divide $Dg$, since it is not $t - \alpha$. But by induction $g$ and $Dg$ are coprime. Hence $f$ and $Df$ are coprime, as required. \[\square\]

We now prove that separability of an irreducible polynomial is automatic over $C$.

**PROPOSITION 9.14**

If $K$ is a subfield of $C$, then every irreducible polynomial over $K$ is separable.

**PROOF** An irreducible polynomial $f$ over $K$ is inseparable if and only if $f$ and $Df$ have a common factor of degree $\geq 1$. If so, then since $f$ is irreducible the common
factor must be $f$, but $Df$ has smaller degree than $f$, and the only multiple of $f$ having smaller degree is $0$, so $Df = 0$. Thus if

$$f(t) = a_0 + \cdots + a_m t^m$$

then this is equivalent to $na_n = 0$ for all integers $n > 0$. For subfields of $\mathbb{C}$, this is equivalent to $a_n = 0$ for all $n$.

---

## Exercises

9.1 Determine splitting fields over $\mathbb{Q}$ for the polynomials $t^3 - 1$, $t^4 + 5t^2 + 6$, $t^6 - 8$, in the form $\mathbb{Q}(\alpha_1, \ldots, \alpha_k)$ for explicit $\alpha_j$.

9.2 Find the degrees of these fields as extensions of $\mathbb{Q}$.

9.3 Prove that the formal derivative $D$ has the following properties:
   a. $D(f + g) = Df + Dg$
   b. $D(fg) = (Df)g + f(Dg)$
   c. If $f(t) = t^n$, then $Df(t) = nt^{n-1}$

9.4 Show that we can extend the definition of the formal derivative to $K(t)$ by defining

$$D(f/g) = (Df \cdot g - f \cdot Dg)/g^2$$

when $g \neq 0$. Verify the relevant properties of $D$.

9.5 Which of the following extensions are normal?
   a. $\mathbb{Q}(t) : \mathbb{Q}$
   b. $\mathbb{Q}(-\sqrt{5}) : \mathbb{Q}$
   c. $\mathbb{Q}(\alpha) : \mathbb{Q}$, where $\alpha$ is the real seventh root of $5$
   d. $\mathbb{Q}(\sqrt{5}, \alpha) : \mathbb{Q}(\alpha)$, where $\alpha$ is as in (c)
   e. $\mathbb{R}(-\sqrt{2}) : \mathbb{R}$

9.6 Show that every extension in $\mathbb{C}$ of degree $2$ is normal. Is this true if the degree is greater than $2$?

9.7 If $\Sigma$ is the splitting field for $f$ over $K$ and $K \subseteq L \subseteq \Sigma$, show that $\Sigma$ is the splitting field for $f$ over $L$.

9.8* Let $f$ be a polynomial of degree $n$ over $K$, and let $\Sigma$ be the splitting field for $f$ over $K$. Show that $[\Sigma : K]$ divides $n!$ (Hint: Use induction on $n$. Consider
9.9 Mark the following true or false.

a. Every polynomial over \( \mathbb{Q} \) splits over some subfield of \( \mathbb{C} \).
b. Splitting fields in \( \mathbb{C} \) are unique.
c. Every finite extension is normal.
d. \( \mathbb{Q}(\sqrt{19}) : \mathbb{Q} \) is a normal extension.
e. \( \mathbb{Q}(\sqrt{19}) : \mathbb{Q} \) is a normal extension.
f. \( \mathbb{Q}(\sqrt{19}) : \mathbb{Q}(\sqrt{19}) \) is a normal extension.
g. A normal extension of a normal extension is a normal extension.
Chapter 10

Counting Principles

When proving the Fundamental Theorem of Galois theory in Chapter 12, we will need to show that if \( H \) is a subgroup of the Galois group of a finite normal extension \( L : K \), then \( H^{\dagger*} = H \). Here the maps \( * \) and \( \dagger \) are as defined in Section 8.6. Our method will be to show that \( H \) and \( H^{\dagger*} \) are finite groups and have the same order. Since we already know that \( H \subseteq H^{\dagger*} \), the two groups must be equal. This is an archetypal application of a counting principle: showing that two finite sets, one contained in the other, are identical by counting how many elements they have, and showing that the two numbers are the same.

It is largely for this reason that we need to restrict attention to finite extensions and finite groups. If an infinite set is contained in another of the same cardinality, they need not be equal; for example, \( \mathbb{Z} \subseteq \mathbb{Q} \) and both sets are countable, but \( \mathbb{Z} \neq \mathbb{Q} \). So counting principles may fail for infinite sets.

The object of this chapter is to perform part of the calculation of the order of \( H^{\dagger*} \). Namely, we find the degree \( [H^{\dagger} : K] \) in terms of the order of \( H \). In Chapter 11 we find the order of \( H^{\dagger*} \) in terms of this degree, putting the pieces together will give the desired result.

10.1 Linear Independence of Monomorphisms

We begin with a theorem of Dedekind, who was the first to make a systematic study of field monomorphisms.

To motivate the theorem and its proof, we consider a special case. Suppose that \( K \) and \( L \) are subfields of \( \mathbb{C} \), and let \( \lambda \) and \( \mu \) be monomorphisms \( K \rightarrow L \). We claim that \( \lambda \) cannot be a constant multiple of \( \mu \) unless \( \lambda = \mu \). By “constant” here we mean an element of \( L \). Suppose that there exists \( a \in L \) such that

\[
\mu(x) = a\lambda(x)
\]

for all \( x \in K \). Replace \( x \) by \( yx \), where \( y \in K \), to get

\[
\mu(yx) = a\lambda(yx)
\]

Since \( \lambda \) and \( \mu \) are monomorphisms, this implies that

\[
\mu(y)\mu(x) = a\lambda(y)\lambda(x)
\]
But we also have

$$\lambda(y)\mu(x) = a\lambda(y)\lambda(x)$$

Comparing the two, we see that $\lambda(y) = \mu(y)$ for all $y$; that is, $\lambda = \mu$.

In other words, if $\lambda$ and $\mu$ are distinct monomorphisms $K \to L$, they must be linearly independent over $L$.

Now suppose that $\lambda_1, \lambda_2, \lambda_3$ are three distinct monomorphisms $K \to L$, and assume that they are linearly dependent over $L$. That is,

$$a_1\lambda_1 + a_2\lambda_2 + a_3\lambda_3 = 0$$

for $a_j \in L$. In more detail,

$$a_1\lambda_1(x) + a_2\lambda_2(x) + a_3\lambda_3(x) = 0 \quad (10.1)$$

for all $x \in K$. If some $a_j = 0$, then we reduce to the previous case, so we may assume all $a_j \neq 0$.

Substitute $yx$ for $x$ in Equation (10.1) to get

$$a_1\lambda_1(yx) + a_2\lambda_2(yx) + a_3\lambda_3(yx) = 0 \quad (10.2)$$

That is,

$$[a_1\lambda_1(y)]\lambda_1(x) + [a_2\lambda_2(y)]\lambda_2(x) + [a_3\lambda_3(y)]\lambda_3(x) = 0 \quad (10.3)$$

Relations (10.1) and (10.3) are independent unless $\lambda_1(y) = \lambda_2(y) = \lambda_3(y)$, and we can choose $y$ to prevent this. Therefore, we may eliminate one of the $\lambda_j$ to deduce a linear relation between at most two of them, contrary to the previous case. Specifically, there exists $y \in K$ such that $\lambda_1(y) \neq \lambda_3(y)$. Multiply Equation (10.1) by $\lambda_3(y)$ and subtract from Equation (10.3) to get

$$[a_1\lambda_1(y) - a_1\lambda_3(y)]\lambda_1(x) + [a_2\lambda_2(y) - a_2\lambda_3(y)]\lambda_2(x) = 0$$

Then the coefficient of $\lambda_1(x)$ is $a_1(\lambda_1(y) - \lambda_3(y)) \neq 0$, a contradiction.

Dedekind realised that this approach can be used inductively to prove:

**LEMMA 10.1 (Dedekind)**

If $K$ and $L$ are subfields of $\mathbb{C}$, then every set of distinct monomorphisms $K \to L$ is linearly independent over $L$.

**PROOF** Let $\lambda_1, \ldots, \lambda_n$ be distinct monomorphisms $K \to L$. To say these are linearly independent over $L$ is to say that there do not exist elements $a_1, \ldots, a_n \in L$ such that

$$a_1\lambda_1(x) + \cdots + a_n\lambda_n(x) = 0 \quad (10.4)$$

for all $x \in K$, unless all the $a_j$ are 0.
10.1 Linear Independence of Monomorphisms

Assume the contrary, so that Equation (10.4) holds. At least one of the $a_i$ is nonzero. Among all the valid equations of the form Equation (10.4) with all $a_i \neq 0$, there must be at least one for which the number $n$ of nonzero terms is least. Since all $\lambda_i$ are nonzero, $n \neq 1$. We choose notation so that Equation (10.4) is such an expression. Hence we may assume that there does not exist an equation like Equation (10.4) with fewer than $n$ terms. We shall then deduce a contradiction.

Since $\lambda_1 \neq \lambda_n$, there exists $y \in K$ such that $\lambda_1(y) \neq \lambda_n(y)$. Therefore, $y \neq 0$. Now Equation (10.4) holds with $yx$ in place of $x$, so

$$a_1 \lambda_1(yx) + \cdots + a_n \lambda_n(yx) = 0$$

for all $x \in K$, whence

$$a_1 \lambda_1(y) \lambda_1(x) + \cdots + a_n \lambda_n(y) \lambda_n(x) = 0 \quad (10.5)$$

for all $x \in K$. Multiply Equation (10.4) by $\lambda_1(y)$ and subtract Equation (10.5) to obtain

$$a_2[\lambda_2(x) \lambda_1(y) - \lambda_2(x) \lambda_1(y)] + \cdots + a_n[\lambda_n(x) \lambda_1(y) - \lambda_n(x) \lambda_n(y)] = 0$$

The coefficient of $\lambda_n(x)$ is $a_n[\lambda_1(y) - \lambda_n(y)] \neq 0$, so we have an equation of the form Equation (9.1) with fewer terms. Deleting any zero terms does not alter this statement. This contradicts the italicized assumption above.

Consequently, no equation of the form Equation (9.1) exists, so the monomorphisms are linearly independent.

\[\square\]

**Example 10.2**

Let $K = \mathbb{Q}(\alpha)$ where $\alpha = \sqrt{2} \in \mathbb{R}$. There are three monomorphisms $K \to \mathbb{C}$, namely,

$$\lambda_1(p + q\alpha + r\alpha^2) = p + q\alpha + r\alpha^2$$
$$\lambda_2(p + q\alpha + r\alpha^2) = p + q\omega\alpha + r\omega^2\alpha^2$$
$$\lambda_3(p + q\alpha + r\alpha^2) = p + q\omega^2\alpha + r\omega\alpha^2$$

where $p, q, r \in \mathbb{Q}$ and $\omega$ is a primitive cube root of unity. We prove by "bare hands" methods that the $\lambda_j$ are linearly independent. Suppose that $a_1\lambda_1(x) + a_2\lambda_2(x) + a_3\lambda_3(x) = 0$ for all $x \in K$. Setting $x = 1, \alpha, \alpha^2$, respectively, we get

$$a_1 + a_2 + a_3 = 0$$
$$a_1 + \omega a_2 + \omega^2 a_3 = 0$$
$$a_1 + \omega^2 a_2 + \omega a_3 = 0$$

The only solution of this system of linear equations is $a_1 = a_2 = a_3 = 0$.
For our next result we need two lemmas. The first is a standard theorem of linear algebra, which we quote without proof.

**Lemma 10.3**
If \( n > m \), then a system of \( m \) homogeneous linear equations

\[
a_{m1}x_1 + \cdots + a_{mn}x_n = 0
\]

in \( n \) unknowns \( x_1, \ldots, x_n \), with complex coefficients \( a_{ij} \), has a solution in which the \( x_i \) are not all zero.

This theorem is proved in most first-year undergraduate linear algebra courses and can be found in any text of linear algebra, for example, Anton (1987).

The second lemma states a useful general principle.

**Lemma 10.4**
If \( G \) is a group whose distinct elements are \( g_1, \ldots, g_n \), and if \( g \in G \), then as \( j \) varies from 1 to \( n \) the elements \( gg_j \) run through the whole of \( G \), each element of \( G \) occurring precisely once.

**Proof** If \( h \in G \), then \( g^{-1}h = g_j \) for some \( j \) and \( h = gg_j \). If \( gg_i = gg_j \), then \( g_i = g^{-1}gg_i = g^{-1}gg_j = g_j \). Thus the map \( g_i \mapsto gg_i \) is a bijection \( G \to G \), and the result follows.

We also recall some standard notation. We denote the cardinality of a set \( S \) by \(|S|\). Thus if \( G \) is a group, then \(|G|\) is the order of \( G \). For example, \(|S_n| = n!\) and \(|A_n| = n!/2\).

We now come to the main theorem of this chapter, whose proof is similar to that of Lemma 10.1, and which can be motivated in a similar manner.

**Theorem 10.5**
Let \( G \) be a finite subgroup of the group of automorphisms of a field \( K \), and let \( K_0 \) be the fixed field of \( G \). Then \([K : K_0] = |G|\).

**Proof** Let \( n = |G| \), and suppose that the elements of \( G \) are \( g_1, \ldots, g_n \), where \( g_1 = 1 \).

1. Suppose that \([K : K_0] = m < n\). Let \( \{x_1, \ldots, x_m\} \) be a basis for \( K \) over \( K_0 \). By Lemma 10.3 there exist \( y_1, \ldots, y_n \in K \), not all zero, such that

\[
y_1g_1(x_j) + \cdots + y_ng_n(x_j) = 0
\]

for \( j = 1, \ldots, m \). Let \( x \) be any element of \( K \). Then

\[
x = \alpha_1y_1 + \cdots + \alpha_my_m
\]
where \( \alpha_1, \ldots, \alpha_m \in K_0 \). Hence

\[
y_1 g_1(x) + \cdots + y_n g_n(x) = y_1 g_1 \left( \sum_l \alpha_l x_l \right) + \cdots + y_n g_n \left( \sum_l \alpha_l x_l \right)
\]

\[
= \sum_l \alpha_l \left[ y_1 g_1(x_l) + \cdots + y_n g_n(x_l) \right]
\]

\[
= 0
\]

using Equation (10.6). Hence the distinct monomorphisms \( g_1, \ldots, g_n \) are linearly dependent, contrary to Lemma 1. Therefore, \( m \geq n \).

2. Next, suppose for a contradiction that \([K : K_0] > n\). Then there exists a set of \( n + 1 \) elements of \( K \) that are linearly independent over \( K_0 \); let such a set be \( \{x_1, \ldots, x_{n+1}\} \). By Lemma 10.3 there exist \( y_1, \ldots, y_{n+1} \in K \), not all zero, such that for \( j = 1, \ldots, n \)

\[
y_1 g_j(x_1) + \cdots + y_{n+1} g_j(x_{n+1}) = 0 \quad (10.7)
\]

We shall subject this equation to a combinatorial attack, similar to that used in proving Lemma 10.1. Choose \( y_1, \ldots, y_{n+1} \) so that as few as possible are nonzero, and renumber so that

\[
y_1, \ldots, y_r \neq 0, \quad y_{r+1}, \ldots, y_{n+1} = 0
\]

Equation (10.7) now becomes

\[
y_1 g_j(x_1) + \cdots + y_r g_j(x_r) = 0 \quad (10.8)
\]

Let \( g \in G \), and operate on (10.8) with \( g \). This gives a system of equations

\[
g(y_1) g g_j(x_1) + \cdots + g(y_r) g g_j(x_r) = 0
\]

By Lemma 4, as \( j \) varies, this system of equations is equivalent to the system

\[
g(y_1) g_j(x_1) + \cdots + g(y_r) g_j(x_r) = 0 \quad (10.9)
\]

Multiply Equation (10.8) by \( g(y_1) \) and Equation (10.9) by \( y_1 \) and subtract, to get

\[
[y_2 g(y_1) - g(y_2) y_1] g_j(x_2) + \cdots + [y_r g(y_1) - g(y_r) y_1] g_j(x_r) = 0
\]

This is a system of equations like Equation (10.8) but with fewer terms, which gives a contradiction unless all the coefficients

\[
y_i g(y_1) - y_1 g(y_i)
\]

are zero. If this happens, then

\[
y_i y_i^{-1} = g(y_i y_i^{-1})
\]
for all \( g \in G \), so that \( y_j y_1^{-1} \in K_0 \). Thus there exist \( z_1, \ldots, z_r \in K_0 \) and an element \( k \in K \) such that \( y_i = k z_i \) for all \( i \). Then Equation (10.8), with \( j = 1 \), becomes

\[
x_1 k z_1 + \cdots + x_r k z_r = 0
\]

and since \( k \neq 0 \) we may divide by \( k \), which shows that the \( x_i \) are linearly dependent over \( K_0 \). This is a contradiction.

Therefore, \( [K : K_0] \) is not greater than \( n \), so by the first part of the proof, \( [K : K_0] = n = |G| \) as required.

\[\]

**COROLLARY 10.6**

If \( G \) is the Galois group of the finite extension \( L : K \), and \( H \) is a finite subgroup of \( G \), then

\[
[H : K] = [L : K]/|H|
\]

**PROOF**  By the tower law, \( [L : K] = [L : H][H : K] \), so \( [H : K] = [L : K]/[L : H] \). But this equals \( [L : K]/|H| \) by Theorem 10.5.

**Example 10.7**

We illustrate Theorem 10.5 by two examples, one simple, the other more intricate.

1. Let \( G \) be the group of automorphisms of \( \mathbb{C} \) consisting of the identity and complex conjugation. The fixed field of \( G \) is \( \mathbb{R} \), for if \( x - iy = x + iy \) \( (x, y \in \mathbb{R}) \) then \( y = 0 \), and conversely. Hence \( [\mathbb{C} : \mathbb{R}] = |G| = 2 \), a conclusion which is manifestly correct.

2. Let \( K = \mathbb{Q}(\zeta) \) where \( \zeta = \exp(2\pi i/5) \in \mathbb{C} \). Now \( \zeta^5 = 1 \) and \( \mathbb{Q}(\zeta) \) consists of all elements

\[
p + q \zeta + r \zeta^2 + s \zeta^3 + t \zeta^4
\]

where \( p, q, r, s, t \in \mathbb{Q} \). The Galois group of \( \mathbb{Q}(\zeta) : \mathbb{Q} \) is easy to find, for if \( \alpha \) is a \( \mathbb{Q} \)-automorphism of \( \mathbb{Q}(\zeta) \) then

\[
(\alpha(\zeta))^5 = \alpha(\zeta^5) = \alpha(1) = 1,
\]

so that \( \alpha(\zeta) = \zeta, \zeta^2, \zeta^3, \) or \( \zeta^4 \). This gives four candidates for \( \mathbb{Q} \)-automorphisms:

\[
\alpha_1 : p + q \zeta + r \zeta^2 + s \zeta^3 + t \zeta^4 \mapsto p + q \zeta + r \zeta^2 + s \zeta^3 + t \zeta^4
\]

\[
\alpha_2 : \mapsto p + s \zeta + q \zeta^2 + t \zeta^3 + r \zeta^4
\]

\[
\alpha_3 : \mapsto p + r \zeta + t \zeta^2 + q \zeta^3 + s \zeta^4
\]

\[
\alpha_4 : \mapsto p + t \zeta + s \zeta^2 + r \zeta^3 + q \zeta^4
\]

It is easy to check that all of these are \( \mathbb{Q} \)-automorphisms. The only point to bear in mind is that \( 1, \zeta, \zeta^2, \zeta^3, \zeta^4 \) are not linearly independent over \( \mathbb{Q} \). However, their linear
relations are generated by just one: $\zeta^2 + \zeta^3 + \zeta^4 = -1$, and this relation is preserved by all of the candidate $\mathbb{Q}$-automorphisms.

Alternatively, observe that $\zeta, \zeta^2, \zeta^3, \zeta^4$ all have the same minimal polynomial $t^4 + t^3 + t^2 + t + 1$ and use Corollary 5.13.

We deduce that the Galois group of $\mathbb{Q}(\zeta) : \mathbb{Q}$ has order 4. It is easy to find the fixed field of this group: it turns out to be $\mathbb{Q}$. Therefore, by Theorem 5, $[\mathbb{Q}(\zeta) : \mathbb{Q}] = 4$. At first sight this might seem wrong, for Equation (10.10) expresses each element in terms of five basic elements; the degree should be 5. In support of this contention, $\zeta$ is a zero of $t^5 - 1$. The astute reader will already have seen the source of this dilemma: $t^5 - 1$ is not the minimal polynomial of $\zeta$ over $\mathbb{Q}$, since it is reducible. The minimal polynomial is, as we have seen, $t^4 + t^3 + t^2 + t + 1$, which has degree 4. Equation (10.10) holds, but the elements of the supposed basis are linearly dependent. Every element of $\mathbb{Q}(\zeta)$ can be expressed uniquely in the form

$$p + q\zeta + r\zeta^2 + s\zeta^3$$

where $p, q, r, s \in \mathbb{Q}$. We did not use this expression because it lacks symmetry and makes the computations formless, and therefore harder.

---

**Exercises**

10.1 Check Theorem 5 for the extensions $\mathbb{C}(t_1, \ldots, t_n) : \mathbb{C}(s_1, \ldots, s_n)$ of Section 8.7.

10.2 Find the fixed field of the subgroup $\{\alpha_1, \alpha_4\}$ for Example 10.7(2). Check that Theorem 5 holds.

10.3 Parallel the argument of Example 10.7(2) when $\zeta = \exp(2\pi i / 7)$.

10.4 Find all monomorphisms $\mathbb{Q} \to \mathbb{C}$.

10.5 Mark the following true or false.

a. If $S \subseteq T$ is a finite set and $|S| = |T|$, then $S = T$.

b. The same is true of infinite sets.

c. There is only one monomorphism $\mathbb{Q} \to \mathbb{Q}$.

d. If $K$ and $L$ are subfields of $\mathbb{C}$, then there exists at least one monomorphism $K \to L$.

e. Distinct automorphisms of a field $K$ are linearly independent over $K$.

f. Linearly independent monomorphisms are distinct.
Chapter 11

Field Automorphisms

The theme of this chapter is the construction of automorphisms to given specifications. We begin with a generalization of a $K$-automorphism, known as a $K$-monomorphism. For normal extensions we shall use $K$-monomorphisms to build up $K$-automorphisms. Using this technique, we can calculate the order of the Galois group of any finite normal extension, which combines with the result of Chapter 10 to give a crucial part of the fundamental theorem of Chapter 12.

We also introduce the concept of a normal closure of a finite extension. This useful device enables us to steer around some of the technical obstructions caused by non-normal extensions.

11.1 $K$-Monomorphisms

We begin by generalizing the concept of a $K$-automorphism of a subfield $L$ of $C$ by relaxing the condition that the map should be onto. We continue to require it to be one-to-one.

**DEFINITION 11.1** Suppose that $K$ is a subfield of each of the subfields $M$ and $L$ of $C$. Then a $K$-monomorphism of $M$ into $L$ is a field monomorphism $\phi : M \to L$ such that $\phi(k) = k$ for every $k \in K$.

**Example 11.2** Suppose that $K = \mathbb{Q}$, $M = \mathbb{Q}(\alpha)$ where $\alpha$ is a real cube root of 2, and $L = \mathbb{C}$. We can define a $K$-monomorphism $\phi : M \to L$ by insisting that $\phi(\alpha) = \omega \alpha$, where $\omega = \exp(2\pi i / 3)$. In more detail, every element of $M$ is of the form $p + q\alpha + r\alpha^2$ where $p, q, r \in \mathbb{Q}$, and

$$\phi(p + q\alpha + r\alpha^2) = p + q\omega \alpha + r\omega^2 \alpha^2$$

Since $\alpha$ and $\omega \alpha$ have the same minimal polynomial, namely, $\alpha^3 - 2$, Corollary 5.13 implies that $\phi$ is a $K$-monomorphism.

There are two other $K$-monomorphisms $M \to L$ in this case. One is the identity, and the other takes $\alpha$ to $\omega^2 \alpha$ (see Figure 11.1).
In general, if $K \subseteq M \subseteq L$, then any $K$-automorphism of $L$ restricts to a $K$-monomorphism $M \to L$. We are particularly interested in when this process can be reversed.

**THEOREM 11.3**
Suppose that $L : K$ is a finite normal extension and $K \subseteq M \subseteq L$. Let $\tau$ be any $K$-monomorphism $M \to L$. Then there exists a $K$-automorphism $\sigma$ of $L$ such that $\sigma|_M = \tau$.

**PROOF** By Theorem 9.9, $L$ is the splitting field over $K$ of some polynomial $f$ over $K$. Hence it is simultaneously the splitting field over $M$ for $f$ and over $\tau(M)$ for $f$. But $\tau|_K$ is the identity, so $\tau(f) = f$. We have the diagram

$$
\begin{array}{ccc}
M & \to & L \\
\tau \downarrow & & \downarrow \sigma \\
\tau(M) & \to & L
\end{array}
$$

with $\sigma$ yet to be found. By Theorem 9.6, there is an isomorphism $\sigma : L \to L$ such that $\sigma|_M = \tau$. Therefore, $\sigma$ is an automorphism of $L$, and since $\sigma|_K = \tau|_K$ is the identity, $\sigma$ is a $K$-automorphism of $L$.

This result can be used to construct $K$-automorphisms. 

**PROPOSITION 11.4**
Suppose that $L : K$ is a finite normal extension and $\alpha, \beta$ are zeros in $L$ of the irreducible polynomial $p$ over $K$. Then there exists a $K$-automorphism $\sigma$ of $L$ such that $\sigma(\alpha) = \beta$.

**PROOF** By Corollary 5.13 there is an isomorphism $\tau : K(\alpha) \to K(\beta)$ such that $\tau|_K$ is the identity and $\tau(\alpha) = \beta$. By Theorem 11.3, $\tau$ extends to a $K$-automorphism $\sigma$ of $L$. 

11.2 Normal Closures

When extensions are not normal, we can try to recover normality by making the extensions larger.

**DEFINITION 11.5** Let $L$ be a finite extension of $K$. A normal closure of $L : K$ is an extension $N$ of $L$ such that

1. $N : K$ is normal.

2. If $L \subseteq M \subseteq N$ and $M : K$ is normal, then $M = N$.

Thus $N$ is the smallest extension of $L$ that is normal over $K$.

The next theorem assures us of a sufficient supply of normal closures, and shows that (working inside $\mathbb{C}$) they are unique.

**THEOREM 11.6**

If $L : K$ is a finite extension in $\mathbb{C}$, then there exists a unique normal closure $N \subseteq \mathbb{C}$ of $L : K$, which is a finite extension of $K$.

**PROOF** Let $x_1, \ldots, x_r$ be a basis for $L$ over $K$, and let $m_j$ be the minimal polynomial of $x_j$ over $K$. Let $N$ be the splitting field for $f = m_1 m_2 \ldots m_r$ over $L$. Then $N$ is also the splitting field for $f$ over $K$, so $N : K$ is normal and finite by Theorem 9.9. Suppose that $L \subseteq P \subseteq N$ where $P : K$ is normal. Each polynomial $m_j$ has a zero $x_j \in P$, so by normality $f$ splits in $P$. Since $N$ is the splitting field for $f$, we have $P = N$. Therefore, $N$ is a normal closure.

Now suppose that $M$ and $N$ are both normal closures. The above polynomial $f$ splits in $M$ and in $N$, so each of $M$ and $N$ contain the splitting field for $f$ over $K$. This splitting field contains $L$ and is normal over $K$, so it must be equal to both $M$ and $N$. 

**Example 11.7**

Consider $\mathbb{Q}(c) : \mathbb{Q}$ where $c$ is the real cube root of 2. This extension is not normal, as we have seen. If we let $K$ be the splitting field for $r^3 - 2$ over $\mathbb{Q}$, contained in $\mathbb{C}$, then $K = \mathbb{Q}(c, \omega, c\omega^2)$ where $\omega = (-1 + i\sqrt{3})/2$ is a complex cube root of unity. This is the same as $\mathbb{Q}(c, \omega)$. Now $K$ is the normal closure for $\mathbb{Q}(c) : \mathbb{Q}$. So here we obtain the normal closure by adjoining all the missing zeros.

Normal closures enable us to place restrictions on the image of a monomorphism.

**LEMMA 11.8**

Suppose that $K \subseteq L \subseteq N \subseteq M$ where $L : K$ is finite and $N$ is the normal closure of $L : K$. Let $\tau$ be any $K$-monomorphism $L \rightarrow M$. Then $\tau(L) \subseteq N$. 
PROOF Let $\alpha \in L$. Let $m$ be the minimal polynomial of $\alpha$ over $K$. Then $m(\alpha) = 0$ so $\tau(m(\alpha)) = 0$. But $\tau(m(\alpha)) = m(\tau(\alpha))$ since $\tau$ is a $K$-monomorphism, so $m(\tau(\alpha)) = 0$ and $\tau(\alpha)$ is a zero of $m$. Therefore, $\tau(\alpha)$ lies in $N$ since $N : K$ is normal. Therefore, $\tau(L) \subseteq N$.

This result often allows us to restrict our attention to the normal closure of a given extension when discussing monomorphisms. The next theorem provides a sort of converse.

THEOREM 11.9
For a finite extension $L : K$ the following are equivalent:

1. $L : K$ is normal.

2. There exists a finite normal extension $N$ of $K$ containing $L$ such that every $K$-monomorphism $\tau : L \to N$ is a $K$-automorphism of $L$.

3. For every finite extension $M$ of $K$ containing $L$, every $K$-monomorphism $\tau : L \to M$ is a $K$-automorphism of $L$.

PROOF We show that $(1) \Rightarrow (3) \Rightarrow (2) \Rightarrow (1)$.

$(1) \Rightarrow (3)$. If $L : K$ is normal, then $L$ is the normal closure of $L : K$, so by Lemma 8, $\tau(L) \subseteq L$. But $\tau$ is a $K$-linear map defined on the finite-dimensional vector space $L$ over $K$, and is a monomorphism. Therefore, $\tau(L)$ has the same dimension as $L$, whence $\tau(L) = L$ and $\tau$ is a $K$-automorphism of $L$.

$(3) \Rightarrow (2)$. Let $N$ be the normal closure for $L : K$. Then $N$ exists by Theorem 11.6, and has the requisite properties by $(3)$.

$(2) \Rightarrow (1)$. Suppose that $f$ is any irreducible polynomial over $K$ with a zero $\alpha \in L$. Then $f$ splits over $\bar{N}$ by normality, and if $\beta$ is any zero of $f$ in $N$, then by Proposition 11.4 there exists an automorphism $\sigma$ of $N$ such that $\sigma(\alpha) = \beta$. By hypothesis, $\sigma$ is a $K$-automorphism of $L$, so $\beta = \sigma(\alpha) \in \sigma(L) = L$. Therefore, $f$ splits over $L$ and $L : K$ is normal.

Our next result is of a more computational nature.

THEOREM 11.10
Suppose that $L : K$ is a finite extension of degree $n$. Then there are precisely $n$ distinct $K$-monomorphisms of $L$ into the normal closure $\bar{N}$ of $L : K$, and hence into any given normal extension $M$ of $K$ containing $L$.

PROOF We use induction on $[L : K]$. If $[L : K] = 1$, then the result is clear. Suppose that $[L : K] = k > 1$. Let $\alpha \in L \setminus K$ with minimal polynomial $m$ over $K$. Then

$$\deg m = [K(\alpha) : K] = r > 1$$
11.2 Normal Closures

Now $m$ is an irreducible polynomial over a subfield of $C$ with one zero in the normal extension $N$, so $m$ splits in $N$ and its zeros $\alpha_1, \ldots, \alpha_r$ are distinct. By induction there are precisely $s$ distinct $K(\alpha)$-monomorphisms $\rho_1, \ldots, \rho_s : L \to N$, where $s = [L : K(\alpha)] = k/r$. By Proposition 11.4, there are $r$ distinct $K$-automorphisms $\tau_1, \ldots, \tau_r$ of $N$ such that $\tau_i(\alpha) = \alpha_i$. The maps

$$\phi_{ij} = \tau_i \rho_j$$

give $rs = k$ distinct $K$-monomorphisms $L \to N$. We show that these exhaust the $K$-monomorphisms $L \to N$.

Let $\tau : L \to N$ be a $K$-monomorphism. Then $\tau(\alpha)$ is a zero of $m$ in $N$, so $\tau(\alpha) = \alpha_i$ for some $i$. The map $\phi = \tau_i^{-1} \tau$ is a $K(\alpha)$-monomorphism $L \to N$, so by induction $\phi = \rho_j$ for some $j$. Hence $\tau = \tau_i \rho_j = \phi_{ij}$ and the theorem is proved.

We can now calculate the order of the Galois group of a finite normal extension, a result of fundamental importance.

**COROLLARY 11.11**

If $L : K$ is a finite normal extension inside $C$, then there are precisely $[L : K]$ distinct $K$-automorphisms of $L$. That is,

$$|\text{Aut}(L : K)| = [L : K]$$

**PROOF** Use Theorems 11.9 and 11.10.

From this we easily deduce the important Theorem 11.12.

**THEOREM 11.12**

Let $L : K$ be a finite extension with Galois group $G$. If $L : K$ is normal, then $K$ is the fixed field of $G$.

**PROOF** Let $K_0$ be the fixed field of $G$, and let $[L : K] = n$. Corollary 11 implies that $|G| = n$. By Theorem 10.5, $[L : K_0] = n$. Since $K \subseteq K_0$ we must have $K = K_0$.

There is a converse to this result, which shows why we must consider normal extensions in order to make the Galois correspondence a bijection. Before we can prove the converse, we need a theorem whose statement and proof closely resemble those of Theorem 11.10.

**THEOREM 11.13**

Suppose that $K \subseteq L \subseteq M$ and $M : K$ is finite. Then the number of distinct $K$-monomorphisms $L \to M$ is at most $[L : K]$.
PROOF Let $N$ be a normal closure of $M : K$. Then $N : K$ is finite by Theorem 11.6, and every $K$-monomorphism $L \to M$ is also a $K$-monomorphism $L \to N$. Hence we may assume that $M$ is a normal extension of $K$ by replacing $M$ by $N$. We now argue by induction on $[L : K]$ as in the proof of Theorem 11.10 except that we can now deduce only that there are $s'$ $K(\alpha)$-monomorphisms $L \to N$, where $s' \leq s$ (by induction) and there are $r'$ distinct $K$-automorphisms of $N$, where $r' \leq r$ (since the zeros of $m$ in $N$ need not be distinct). The rest of the argument goes through as before. 

THEOREM 11.14
If $L : K$ is a finite extension with Galois group $G$, such that $K$ is the fixed field of $G$, then $L : K$ is normal.

PROOF By Theorem 10.5, $[L : K] = |G| = n$, say. There are exactly $n$ distinct $K$-monomorphisms $L \to L$, namely, the elements of the Galois group.

We prove normality using Theorem 11.9. Thus let $N$ be an extension of $K$ containing $L$, and let $\tau$ be a $K$-monomorphism $L \to N$. Since every element of the Galois group of $L : K$ defines a $K$-monomorphism $L \to N$, the Galois group provides $n$ $K$-monomorphisms $L \to N$, and these are automorphisms of $L$. But by Theorem 11.13 there are at most $n$ distinct $K$-monomorphisms $\tau$, so $\tau$ must be one of these monomorphisms. Hence $\tau$ is an automorphism of $L$. Finally, by Theorem 11.9, $L : K$ is normal. 

If the Galois correspondence is a bijection, then $K$ must be the fixed field of the Galois group of $L : K$, so by the above $L : K$ must be normal. That these hypotheses are also sufficient to make the Galois correspondence bijective (for subfields of $\mathbb{C}$) will be proved in Chapter 12. For general fields we need the additional concept of separability (see Chapter 17).

Exercises

11.1 Suppose that $L : K$ is finite. Show that every $K$-monomorphism $L \to L$ is an automorphism. Does this result hold if the extension is not finite?

11.2 Construct the normal closure $N$ for the following extensions.
   a. $\mathbb{Q}(\alpha) : \mathbb{Q}$ where $\alpha$ is the real fifth root of 3
   b. $\mathbb{Q}(\beta) : \mathbb{Q}$ where $\beta$ is the real seventh root of 2
   c. $\mathbb{Q}(\sqrt{2}, \sqrt{3}) : \mathbb{Q}$
   d. $\mathbb{Q}(\alpha, \sqrt{2}) : \mathbb{Q}$ where $\alpha$ is the real cube root of 2
   e. $\mathbb{Q}(\gamma) : \mathbb{Q}$ where $\gamma$ is a zero of $t^3 - 3t^2 + 3$
11.3 Find the Galois groups of the extensions (a), (b), (c), (d) in Exercise 11.2.

11.4 Find the Galois groups of the extensions \( N : \mathbb{Q} \) for their normal closures \( N \).

11.5 Show that Lemma 11.8 fails if we do not assume that \( N : K \) is normal, but is true for any extension \( N \) of \( L \) such that \( N : K \) is normal, rather than just for a normal closure.

11.6 Use Corollary 11.11 to find the order of the Galois group of the extension \( \mathbb{Q}(\sqrt{3}, \sqrt{5}, \sqrt{7}) : \mathbb{Q} \). (Hint: Argue as in Example 6.8.)

11.7 Mark the following true or false.

a. Every \( K \)-monomorphism is a \( K \)-automorphism.

b. Every finite extension has a normal closure.

c. If \( K \subseteq L \) and \( \sigma \) is a \( K \)-automorphism of \( L \), then the restriction \( \sigma|_K \) is a \( K \)-automorphism of \( K \).

d. An extension having Galois group of order 1 is normal.

e. A finite normal extension has finite Galois group.

f. Every Galois group is abelian (commutative).

g. The Galois correspondence fails for non-normal extensions.

h. A finite normal extension inside \( \mathbb{C} \), of degree \( n \), has a Galois group of order \( n \).

i. The Galois group of a normal extension is cyclic.
Chapter 12

The Galois Correspondence

We are at last in a position to establish the fundamental properties of the Galois correspondence between a field extension and its Galois group. Most of the work has already been done, and all that remains is to put the pieces together.

12.1 The Fundamental Theorem

Let us recall a few points of notation from Chapter 8. Let $L : K$ be a field extension in $\mathbb{C}$ with Galois group $G$, which consists of all $K$-automorphisms of $L$. Let $\mathcal{F}$ be the set of intermediate fields, that is, subfields $M$ such that $K \subseteq M \subseteq L$, and let $\mathcal{G}$ be the set of all subgroups $H$ of $G$. We have defined two maps

* : $\mathcal{F} \rightarrow \mathcal{G}$
+ : $\mathcal{G} \rightarrow \mathcal{F}$

as follows: if $M \in \mathcal{F}$, then $M^*$ is the group of all $M$-automorphisms of $L$. If $H \in \mathcal{G}$, then $H^+$ is the fixed field of $H$. We have observed that the maps * and + reverse inclusions, that is, $M \subseteq M^*$ and $H \subseteq H^+$.

THEOREM 12.1 (Fundamental Theorem of Galois Theory)
If $L : K$ is a finite normal field extension inside $\mathbb{C}$, with Galois group $G$, and if $\mathcal{F}$, $\mathcal{G}$, *, + are defined as above, then:

1. The Galois group $G$ has order $[L : K]$.

2. The maps * and + are mutual inverses, and set up an order-reversing one-to-one correspondence between $\mathcal{F}$ and $\mathcal{G}$.

3. If $M$ is an intermediate field, then

4. An intermediate field $M$ is a normal extension of $K$ if and only if $M^*$ is a normal subgroup of $G$.

5. If an intermediate field $M$ is a normal extension of $K$, then the Galois group of $M : K$ is isomorphic to the quotient group $G/M^*$.
**PROOF** The first part is a restatement of Corollary 11.11. For the second part, Theorem 9.9 implies that $L : M$ is normal. Now Theorem 11.12 implies that $M$ is the fixed field of $M^*$, so

$$M^* = M$$

(12.1)

Now consider $H \in \mathcal{G}$. We know that $H \subseteq H^*$. Therefore, $H^* = (H^*)^* = H^*$ by (12.1). By Theorem 10.5, $|H| = [L : H^*]$. Therefore, $|H| = [L : H^*]$, and by Theorem 10.5 again, $[L : H^*] = [H^*]$ so that $|H| = [H^*]$. Since $H$ and $H^*$ are finite groups and $H \subseteq H^*$, we must have $H = H^*$. The second part of Theorem 12.1 follows at once.

For the third part, we again note that $L : M$ is normal. Corollary 11.11 states that $[L : M] = |M^*|$, and the other equality follows immediately.

To prove the last two parts of Theorem 12.1 we require a lemma.

**Lemma 12.2**

Suppose that $L : K$ is a field extension, $M$ is an intermediate field, and $\tau$ is a $K$-automorphism of $L$. Then $\tau(M^*) = \tau M^* \tau^{-1}$.

**Proof** Let $M' = \tau(M)$, and take $\gamma \in M^*$, $x_1 \in M'$. Then $x_1 = \tau(x)$ for some $x \in M$. Compute:

$$(\tau \gamma \tau^{-1})(x_1) = \tau \gamma(x) = \tau(x) = x_1$$

so $\tau M^* \tau^{-1} \subseteq M^*$. Similarly, $\tau^{-1} M^* \tau \subseteq M^*$, so $\tau M^* \tau^{-1} \supseteq M^*$, and the lemma is proved.

We now prove the fourth part of Theorem 12.1. If $M : K$ is normal, let $\tau \in \mathcal{G}$. Then $\tau|_M$ is a $K$-monomorphism $M \rightarrow L$, so is a $K$-automorphism of $M$ by Theorem 11.9. Hence $\tau(M) = M$. By Lemma 12.2, $\tau M^* \tau^{-1} = M^*$, so $M^*$ is a normal subgroup of $G$.

Conversely, suppose that $M^*$ is a normal subgroup of $G$. Let $\sigma$ be any $K$-monomorphism $M \rightarrow L$. By Theorem 11.3, there is a $K$-automorphism $\tau$ of $L$ such that $\tau|_M = \sigma$. Now $\tau M^* \tau^{-1} = M^*$ since $M^*$ is a normal subgroup of $G$, so by Lemma 12.2, $\tau(M)^* = M^*$. By part 2 of Theorem 12.1, $\tau(M) = M$. Hence $\sigma(M) = M$ and $\sigma$ is a $K$-automorphism of $M$. By Theorem 11.9, $M : K$ is normal.

Now we prove the final part of the theorem. Let $G'$ be the Galois group of $M : K$. We can define a map $\phi : G \rightarrow G'$ by

$$\phi(\tau) = \tau|_M \quad \tau \in G$$

This is clearly a group homomorphism $G \rightarrow G'$, for by Theorem 11.9 $\tau|_M$ is a $K$-automorphism of $M$ By Theorem 11.3, $\phi$ is onto The kernel of $\phi$ is obviously $M^*$.
so by standard group theory

\[ G' = \text{im}(\phi) \cong G/\ker(\phi) = G/M^* \]

where im is the image and ker the kernel.

Note how Theorem 10.5 is used in the proof of part 2 of Theorem 12.1; its use is crucial. Many of the most beautiful results in mathematics hang by equally slender threads.

Parts (4) and (5) of Theorem 12.1 can be generalized (see Exercise 12.2). Note that the proof of part 5 provides an explicit isomorphism between \( \Gamma(M : K) \) and \( G/M^* \), namely, restriction to \( M \).

The importance of the Fundamental Theorem of Galois Theory derives from its potential as a tool rather than its intrinsic merit. It enables us to apply group theory to otherwise intractable problems about polynomials over \( \mathbb{C} \) and associated subfields of \( \mathbb{C} \), and we spend most of the remaining chapters exploiting such applications. But before venturing further we consolidate our position by illustrating the whole theory for a particular field extension and its Galois group. Chapter 13 is devoted to this end.

---

**Exercises**

12.1 Work out the details of the Galois correspondence for the extension

\[ \mathbb{Q}(i, \sqrt{5}) : \mathbb{Q} \]

whose Galois group is \( G = \{ I, R, S, T \} \) as in Chapter 8.

12.2 Let \( L : K \) be a finite normal extension in \( \mathbb{C} \) with Galois group \( G \). Suppose that \( M, N \) are intermediate fields with \( M \subset N \). Prove that \( N : M \) is normal if and only if \( N^* \) is a normal subgroup of \( M^* \). In this case prove that the Galois group of \( N : M \) is isomorphic to \( M^*/N^* \).

12.3* Let \( \gamma = \sqrt{2 + \sqrt{2}} \). Show that \( \mathbb{Q}(\gamma) : \mathbb{Q} \) is normal, with cyclic Galois group. Show that \( \mathbb{Q}(\gamma, i) = \mathbb{Q}(\phi) \) where \( \phi^4 = i \).

12.4* Find the Galois group of \( t^6 - 7 \) over \( \mathbb{Q} \).

12.5* Find the Galois group of \( t^6 - 2t^3 - 1 \) over \( \mathbb{Q} \).

12.6 Mark the following true or false.

a. If \( L : K \) is a finite normal extension inside \( \mathbb{C} \), then the order of the Galois group of \( L : K \) is equal to the dimension of \( L \) considered as a vector space over \( K \).

b. If \( M \) is any intermediate field of a finite normal extension inside \( \mathbb{C} \), then \( M^{1*} = M \).
c. If $M$ is any intermediate field of a finite normal extension inside $\mathbb{C}$, then $M^{\ast\dagger} = M$.

d. If $M$ is any intermediate field of a finite normal extension $L : K$ inside $\mathbb{C}$, then the Galois group of $M : K$ is a subgroup of the Galois group of $L : K$.

e. If $M$ is any intermediate field of a finite normal extension $L : K$ inside $\mathbb{C}$, then the Galois group of $L : M$ is a quotient of the Galois group of $L : K$. 
Chapter 13

A Worked Example

The Fundamental Theorem of Galois theory is quite a lot to take in at one go, so it is worth spending some time thinking it through. We, therefore, analyse how the Galois correspondence works out on an extended example.

The extension that we discuss is a favourite with writers on Galois theory, because of its archetypal quality. A simpler example would be too small to illustrate the theory adequately, and anything more complicated would be unwieldy. The example is the Galois group of the splitting field of $t^4 - 2$ over $\mathbb{Q}$.

The discussion is cut into small pieces to make it more easily digestible.

1. Let $f(t) = t^4 - 2$ over $\mathbb{Q}$, and let $K$ be a splitting field for $f$ such that $K \subseteq \mathbb{C}$.

We can factorize $f$ as follows:

$$f(t) = (t - \xi)(t + \xi)(t - i\xi)(t + i\xi)$$

where $\xi = \sqrt[4]{2}$ is real and positive. Therefore, $K = \mathbb{Q}(\xi, i)$. Since $K$ is a splitting field, $K : \mathbb{Q}$ is finite and normal. We are working in $\mathbb{C}$, so separability is automatic.

2. We find the degree of $K : \mathbb{Q}$. By the tower law,

$$[K : \mathbb{Q}] = [\mathbb{Q}(\xi, i) : \mathbb{Q}(\xi)][\mathbb{Q}(\xi) : \mathbb{Q}]$$

The minimal polynomial of $i$ over $\mathbb{Q}(\xi)$ is $t^2 + 1$, since $i^2 + 1 = 0$ but $i \notin \mathbb{R} \supseteq \mathbb{Q}(\xi)$. So $[\mathbb{Q}(\xi, i) : \mathbb{Q}(\xi)] = 2$.

Now $\xi$ is a zero of $f$ over $\mathbb{Q}$, and $f$ is irreducible by Eisenstein’s Criterion, Theorem 3.19. Hence $f$ is the minimal polynomial of $\xi$ over $\mathbb{Q}$, and $[\mathbb{Q}(\xi) : \mathbb{Q}] = 4$. Therefore,

$$[K : \mathbb{Q}] = 2.4 = 8$$

3. We shall find the elements of the Galois group of $K : \mathbb{Q}$. By a direct check, or by Corollary 5.13, there is a $\mathbb{Q}$-automorphism $\sigma$ of $K$ such that

$$\sigma(i) = i \quad \sigma(\xi) = i\xi$$

and another, $\tau$, such that

$$\tau(i) = -i \quad \tau(\xi) = \xi$$
Products of these yield eight distinct $\mathbb{Q}$-automorphisms of $K$, as follows:

<table>
<thead>
<tr>
<th>Automorphism</th>
<th>Effect on $\xi$</th>
<th>Effect on $i$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>$\xi$</td>
<td>$i$</td>
</tr>
<tr>
<td>$\sigma$</td>
<td>$i\xi$</td>
<td>$i$</td>
</tr>
<tr>
<td>$\sigma^2$</td>
<td>$-\xi$</td>
<td>$i$</td>
</tr>
<tr>
<td>$\sigma^3$</td>
<td>$-i\xi$</td>
<td>$i$</td>
</tr>
<tr>
<td>$\tau$</td>
<td>$\xi$</td>
<td>$-i$</td>
</tr>
<tr>
<td>$\sigma\tau$</td>
<td>$i\xi$</td>
<td>$-i$</td>
</tr>
<tr>
<td>$\sigma^2\tau$</td>
<td>$-\xi$</td>
<td>$-i$</td>
</tr>
<tr>
<td>$\sigma^3\tau$</td>
<td>$-i\xi$</td>
<td>$-i$</td>
</tr>
</tbody>
</table>

Other products do not give new automorphisms, since $\sigma^4 = 1$, $\tau^2 = 1$, $\tau\sigma = \sigma^3\tau$, $\tau\sigma^2 = \sigma^2\tau$, $\tau\sigma^3 = \sigma\tau$. (The last two relations follow from the first three.)

Now any $\mathbb{Q}$-automorphism of $K$ sends $i$ to some zero of $t^2 + 1$, so $i \mapsto \pm i$; similarly, $\xi$ is mapped to $\xi$, $i\xi$, $-\xi$, or $-i\xi$. All possible combinations of these (eight in number) appear in the above list, so these are precisely the $\mathbb{Q}$-automorphisms of $K$.

4. The abstract structure of the Galois group $G$ can be found. The generator-relation presentation

$$G = \langle \sigma, \tau : \sigma^4 = 1, \tau^2 = 1, \tau\sigma = \sigma^3\tau \rangle$$

shows that $G$ is the dihedral group of order 8, which we write as $\mathbb{D}_8$.

The group $\mathbb{D}_8$ has a geometric interpretation as the symmetry group of a square. In fact, we can label the four vertices of a square with the zeros of $t^4 - 2$, in such a way that the geometric symmetries are precisely the permutations of the zeros that occur in the Galois group (Figure 13.1).

![Figure 13.1: The Galois group $\mathbb{D}_8$ interpreted as the symmetry group of a square.](image-url)
5. It is an easy exercise to find the subgroups of $G$. If as usual we let $\mathbb{Z}_n$ denote the cyclic group of order $n$ and $\times$ the direct product, then the subgroups are as follows:

Order 8: \[ G \cong D_8 \]
Order 4: \[
\begin{align*}
1, \sigma, \sigma^2, \sigma^3 & \quad S \cong \mathbb{Z}_4 \\
1, \sigma^2, \tau, \sigma^2, \tau & \quad T \cong \mathbb{Z}_2 \times \mathbb{Z}_2 \\
1, \sigma^2, \sigma\tau, \sigma^3, \tau & \quad U \cong \mathbb{Z}_2 \times \mathbb{Z}_2
\end{align*}
\]
Order 2: \[
\begin{align*}
1, \sigma^2 & \quad A \cong \mathbb{Z}_2 \\
1, \tau & \quad B \cong \mathbb{Z}_2 \\
1, \sigma\tau & \quad C \cong \mathbb{Z}_2 \\
1, \sigma^2\tau & \quad D \cong \mathbb{Z}_2 \\
1, \sigma^3\tau & \quad E \cong \mathbb{Z}_2
\end{align*}
\]
Order 1: \[ \{1\} \quad I \cong 1 \]

6. The inclusion relations between the subgroups of $G$ can be summed up by the lattice diagram of Figure 13.2. In such diagrams, $X \subseteq Y$ if there is a sequence of upward-sloping lines from $X$ to $Y$.

7. Under the Galois correspondence we obtain the intermediate fields. Since the correspondence reverses inclusions, we obtain the lattice diagram in Figure 13.3.

![Figure 13.2: Lattice of subgroups.](image)

![Figure 13.3: Lattice of subfields.](image)
8. We now describe the elements of these intermediate fields. There are three obvious subfields of $K$ of degree 2 over $\mathbb{Q}$, namely, $\mathbb{Q}(i)$, $\mathbb{Q}(\sqrt{2})$, $\mathbb{Q}(i\sqrt{2})$. These are clearly the fixed fields $S^\dagger$, $T^\dagger$, and $U^\dagger$, respectively. The other fixed fields are less obvious. To illustrate a possible approach we shall find $C^\dagger$. Any element of $K$ can be expressed uniquely in the form

$$x = a_0 + a_1\xi + a_2\xi^2 + a_3\xi^3 + a_4i + a_5i\xi + a_6i\xi^2 + a_7i\xi^3$$

where $a_0, \ldots, a_7 \in \mathbb{Q}$. Then

$$\sigma\tau(x) = a_0 + a_1i\xi - a_2\xi^2 - a_3i\xi^3 - a_4i - a_5(-i)i\xi - a_6i(i\xi)^2 - a_7i(i\xi)^3$$

$$= a_0 + a_5\xi - a_2\xi^2 - a_7\xi^3 - a_4i + a_1i\xi + a_6i\xi^2 - a_3i\xi^3$$

The element $x$ is fixed by $\sigma\tau$ (and hence by $C$) if and only if

$$a_0 = a_0 \quad a_1 = a_5 \quad a_2 = -a_2 \quad a_3 = -a_7$$

$$a_4 = -a_4 \quad a_5 = a_1 \quad a_6 = a_6 \quad a_7 = -a_3$$

Therefore, $a_0$ and $a_6$ are arbitrary, while

$$a_2 = 0 = a_4 \quad a_1 = a_5 \quad a_3 = -a_7$$

It follows that

$$x = a_0 + a_1(1 + i)\xi + a_6i\xi^2 + a_3(1 - i)\xi^3$$

$$= a_0 + a_1[(1 + i)\xi] + \frac{a_6}{2}[(1 + i)\xi]^2 - \frac{a_3}{2}[(1 + i)\xi]^3$$

which shows that

$$C^\dagger = \mathbb{Q}((1 + i)\xi)$$

Similarly,

$$A^\dagger = \mathbb{Q}(i, \sqrt{2}) \quad B^\dagger = \mathbb{Q}(\xi) \quad D^\dagger = \mathbb{Q}(i\xi) \quad E^\dagger = \mathbb{Q}((1 - i)\xi)$$

It is now easy to verify the inclusion relations specified by the lattice diagram in Figure 13.3.

9. It is possible, but tedious, to check by hand that these are the only intermediate fields.

10. The normal subgroups of $G$ are $G$, $S$, $T$, $U$, $A$, $I$. By the Fundamental Theorem of Galois theory, $G^\dagger$, $S^\dagger$, $T^\dagger$, $U^\dagger$, $A^\dagger$, $I^\dagger$ should be the only normal extensions of $\mathbb{Q}$ that are contained in $K$. Since these are all splitting fields over $\mathbb{Q}$, for the polynomials $t$, $t^2 + 1$, $t^2 - 2$, $t^2 + 2$, $t^4 - t^2 - 2$, $t^4 - 2$ (respectively), they are normal extensions of $\mathbb{Q}$. On the other hand, $B^\dagger : \mathbb{Q}$ is not normal, since $t^4 - 2$ has a zero, namely, $\xi$, in $B^\dagger$ but does not split in $B^\dagger$. Similarly, $C^\dagger$, $D^\dagger$, $E^\dagger$ are not normal extensions of $\mathbb{Q}$.
11. According to the Fundamental Theorem of Galois theory, the Galois group of $A^\dagger : Q$ is isomorphic to $G/A$. Now $G/A$ is isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_2$. We calculate directly the Galois group of $A^\dagger : Q$. Since $A^\dagger = Q(i, \sqrt{2})$ there are four $\mathbb{Q}$-automorphisms:

<table>
<thead>
<tr>
<th>Automorphism</th>
<th>Effect on $i$</th>
<th>Effect on $\sqrt{2}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>$i$</td>
<td>$\sqrt{2}$</td>
</tr>
<tr>
<td>$\alpha$</td>
<td>$i$</td>
<td>$-\sqrt{2}$</td>
</tr>
<tr>
<td>$\beta$</td>
<td>$-i$</td>
<td>$\sqrt{2}$</td>
</tr>
<tr>
<td>$\alpha \beta$</td>
<td>$-i$</td>
<td>$-\sqrt{2}$</td>
</tr>
</tbody>
</table>

and since $\alpha^2 = \beta^2 = 1$ and $\alpha \beta = \beta \alpha$, this group is $\mathbb{Z}_2 \times \mathbb{Z}_2$ as expected.

12. Note that the lattice diagrams for $\mathcal{F}$ and $\mathcal{G}$ do not look the same unless one is turned upside-down. Hence there does not exist a correspondence like the Galois correspondence but preserving inclusion relations. It may seem a little odd at first that the Galois correspondence reverses inclusions, but in fact it is entirely natural, and quite as useful a property as preservation of inclusions.

It is in general a difficult problem to compute the Galois group of a given field extension, particularly when there is no explicit representation for the elements of the large field (see Chapter 22).

---

Exercises

13.1 Find the Galois groups of the following extensions:
   a. $Q(\sqrt{2}, \sqrt{5}) : Q$
   b. $Q(\alpha) : Q$ where $\alpha = \exp(2\pi i/3)$
   c. $K : Q$ where $K$ is the splitting field over $Q$ for $t^4 - 3t^2 + 4$.

13.2 Find all subgroups of these Galois groups.

13.3 Find the corresponding fixed fields.

13.4 Find all normal subgroups of the above Galois groups.

13.5 Check that the corresponding extensions are normal.

13.6 Verify that the Galois groups of these normal extensions are the relevant quotient groups.

13.7* Consider the Galois group of $t^6 - 7$ over $Q$ found in Exercise 12.4. Use the Galois correspondence to find all intermediate fields.
13.8* Consider the Galois group of \( t^6 - 2t^3 - 1 \) over \( \mathbb{Q} \) found in Exercise 12.5. Use the Galois correspondence to find all intermediate fields.

13.9 Find the Galois group of \( t^8 - i \) over \( \mathbb{Q}(i) \).

13.10 Find the Galois group of \( t^8 \div t^4 \div 1 \) over \( \mathbb{Q}(i) \).

3.11 Use the Galois group \( \mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2 \) of \( \mathbb{Q}(\sqrt{2}, \sqrt{3}, \sqrt{5}) : \mathbb{Q} \) to find all intermediate fields. Which of these are normal over \( \mathbb{Q} \)?

13.12 Mark the following true or false.

a. A \( 3 \times 3 \) square has exactly 9 distinct symmetries.

b. The symmetry group of a square is isomorphic to \( \mathbb{Z}_8 \).

c. The symmetry group of a square is isomorphic to \( S_8 \).

d. The symmetry group of a square is isomorphic to a subgroup of \( S_8 \).

e. The group \( D_8 \) has 10 distinct subgroups.

f. The Galois correspondence preserves inclusion relations.

g. The Galois correspondence reverses inclusion relations.
Chapter 14

Solubility and Simplicity

In order to apply the Galois correspondence, we need to have at our fingertips a number of group-theoretical concepts and theorems. We have already assumed familiarity with elementary group theory: subgroups, normal subgroups, quotient groups, conjugates, permutations (up to cycle decomposition); to these we now add the standard isomorphism theorems. The relevant theory, along with most of the material in this chapter, can be found in any good textbook of group theory, for example, Fraleigh (1989), Humphreys (1996), or Neumann, Stoy, and Thompson (1994).

We start by defining soluble groups and proving some basic properties. These groups are of cardinal importance for the theory of the solution of equations by radicals. Next, we discuss simple groups, the main target being a proof of the simplicity of the alternating group of degree 5 or more. We end by proving Cauchy’s Theorem: if a prime $p$ divides the order of a finite group, then the group has an element of order $p$.

14.1 Soluble Groups

Soluble groups were first defined and studied (though not in the current abstract way) by Galois in his work on the solution of equations by radicals. They have since proved extremely important in many branches of mathematics.

In the following definition and thereafter, the notation $H \triangleleft G$ will mean that $H$ is a normal subgroup of the group $G$. Recall that an abelian (or commutative) group is one in which $gh = hg$ for all elements $g, h$.

**DEFINITION 14.1** A group $G$ is soluble (in the U.S.: solvable) if it has a finite series of subgroups

\[ 1 = G_0 \subseteq G_1 \subseteq \cdots \subseteq G_n = G \tag{14.1} \]

such that

1. $G_i \triangleleft G_{i+1}$ for $i = 0, \ldots, n - 1$.
2. $G_{i+1}/G_i$ is abelian for $i = 0, \ldots, n - 1$.

Condition (1) does not imply that $G_i \triangleleft G$, since $G_i \triangleleft G_{i+1} \triangleleft G_{i+2}$ does not imply $G_i \triangleleft G_{i+2}$ (see Exercise 14.11).
Example 14.2

1. Every abelian group $G$ is soluble, with series $1 \triangleleft G$.

2. The symmetric group $S_3$ of degree 3 is soluble, since it has a cyclic normal subgroup of order 3 generated by the cycle $(123)$ whose quotient is cyclic of order 2. All cyclic groups are abelian.

3. The dihedral group $D_8$ of order 8 is soluble. In the notation of Chapter 13, it has a normal subgroup $S$ of order 4 whose quotient has order 2, and $S$ is abelian.

4. The symmetric group $S_4$ of degree 4 is soluble, having a series

$$1 \triangleleft V \triangleleft A_4 \triangleleft S_4$$

where $A_4$ is the alternating group of order 12, and $V$ is the Klein four-group, which we recall consists of the permutations $1$, $(12)(34),(13)(24),(14)(23)$ and hence is a direct product of two cyclic groups of order 2. The quotient groups are

$$V/1 \cong V \quad \text{abelian of order 4}$$
$$A_4/V \cong Z_3 \quad \text{abelian of order 3}$$
$$S_4/A_4 \cong Z_2 \quad \text{abelian of order 2}$$

5. The symmetric group $S_5$ of degree 5 is not soluble. This follows from Lemma 8.11 with a bit of extra work. See Corollary 14.8.

We recall the following isomorphism theorems.

Lemma 14.3

Let $G$, $H$, and $A$ be groups.

1. If $H \triangleleft G$ and $A \subseteq G$, then $H \cap A \triangleleft A$ and

$$\frac{A}{H \cap A} \cong \frac{HA}{H}$$

2. If $H \triangleleft G$, and $H \subseteq A \triangleleft G$ then $H \triangleleft A$, $A/H \triangleleft G/H$ and

$$\frac{G/H}{A/H} \cong \frac{G}{A}$$

Parts (1) and (2) are, respectively, the First and Second Isomorphism Theorems. They are the translation into normal subgroup language of two straightforward facts: restricting a homomorphism to a subgroup yields a homomorphism, and composing two homomorphisms yields a homomorphism (see Exercise 14.12).

Judicious use of these isomorphism theorems lets us prove that soluble groups persist in being soluble even when subjected to quite drastic treatment.
**THEOREM 14.4**

Let $G$ be a group, $H$ a subgroup of $G$, and $N$ a normal subgroup of $G$.

1. If $G$ is soluble, then $H$ is soluble.

2. If $G$ is soluble, then $G/N$ is soluble.

3. If $N$ and $G/N$ are soluble, then $G$ is soluble.

**PROOF**

1. Let

\[ 1 = G_0 \triangleleft G_1 \triangleleft \cdots \triangleleft G_r = G \]

be a series for $G$ with abelian quotients $G_{i+1}/G_i$. Let $H_i = G_i \cap H$. Then $H$ has a series

\[ 1 + H_0 \triangleleft \cdots \triangleleft H_r = H \]

We show the quotients are abelian. Now

\[ \frac{H_{i+1}}{H_i} = \frac{G_{i+1} \cap H}{G_i \cap H} = \frac{G_{i+1} \cap H}{G_i \cap (G_{i+1} \cap H)} \cong \frac{G_i(G_{i+1} \cap H)}{G_i} \]

by the first isomorphism theorem. But this latter group is a subgroup of $G_{i+1}/G_i$ which is abelian. Hence $H_{i+1}/H_i$ is abelian for all $i$, and $H$ is soluble.

2. Define $G_i$ as before. Then $G/N$ has a series

\[ N/N = G_0N/N \triangleleft G_1N/N \triangleleft \cdots \triangleleft G_rN/N = G/N \]

A typical quotient is

\[ \frac{G_{i+1}N/N}{G_iN/N} \]

which by the second isomorphism theorem is isomorphic to

\[ \frac{G_{i+1}N}{G_iN} = \frac{G_{i+1}(G_iN)}{G_iN} \cong \frac{G_{i+1}}{G_i \cap (G_{i+1}N)} \cong \frac{G_{i+1}/G_i}{(G_{i+1} \cap (G_iN))/G_i} \]

which is a quotient of the abelian group $G_{i+1}/G_i$, and so is abelian. Therefore, $G/N$ is soluble.

3. There exist two series

\[ 1 = N_0 \triangleleft N_1 \triangleleft \cdots \triangleleft N_r = N \]

\[ N/N = G_0/N \triangleleft G_1/N \triangleleft \cdots \triangleleft G_s/N = G/N \]
with abelian quotients. Consider the series of $G$ given by combining them:

$$1 = N_0 \triangleleft N_1 \triangleleft \cdots \triangleleft N_r = N = G_0 \triangleleft G_1 \triangleleft \cdots \triangleleft G_s = G$$

The quotients are either $N_{i+1}/N_i$ (which is abelian) or $G_{i+1}/G_i$, which is isomorphic to

$$\frac{G_{i+1}/N}{G_i/N}$$

and again is abelian. Therefore, $G$ is soluble.

Let us say that a group $G$ is an extension of a group $A$ by a group $B$ if $G$ has a normal subgroup $N$ isomorphic to $A$ such that $G/N$ is isomorphic to $B$. Then we may sum up the three properties of the above theorem by saying that the class of soluble groups is closed under taking subgroups, quotients, and extensions. The class of abelian groups is closed under subgroups and quotients, but not extensions; and it is largely for this reason that Galois was led to define soluble groups.

---

14.2 Simple Groups

We turn to groups that are, in a sense, the opposite of soluble.

**Definition 14.5** A group $G$ is simple if its only normal subgroups are $1$ and $G$.

Every cyclic group $\mathbb{Z}_p$ of prime order is simple, since it has no subgroups other than $1$ and $\mathbb{Z}_p$, hence in particular no other normal subgroups. These groups are also abelian, hence soluble. They are in fact the only soluble simple groups.

**Theorem 14.6**
A soluble group is simple if and only if it is cyclic of prime order.

**Proof** Since $G$ is a soluble group, it has a series

$$1 = G_0 \triangleleft G_1 \triangleleft \cdots \triangleleft G_n = G$$

where by deleting repeats we may assume $G_{i+1} \neq G_i$. Then $G_{n-1}$ is a proper normal subgroup of $G$. However, $G$ is simple, so $G_{n-1} = 1$ and $G = G_n/G_{n-1}$, which is abelian. Since every subgroup of an abelian group is normal, and every element of $G$ generates a cyclic subgroup, $G$ must be cyclic with no nontrivial proper subgroups. Hence $G$ has prime order.

The converse is trivial.
Simple groups play an important role in finite group theory. They are in a sense the fundamental units from which all finite groups are made. Indeed the Jordan–Hölder theorem, which we do not prove, states that every finite group has a series of subgroups like Equation (14.1) whose quotients are simple, and these simple groups depend only on the group and not on the series chosen.

We do not need to know much about simple groups, intriguing as they are. We require just one result.

**THEOREM 14.7**

If \( n \geq 5 \), then the alternating group \( A_n \) of degree \( n \) is simple.

**PROOF**  We use much the same strategy as in Lemma 8.11, but we are proving a rather stronger property, so we have to work a bit harder.

Suppose that \( I \neq N < A_n \). Our strategy will be as follows: first, observe that if \( N \) contains a 3-cycle then it contains all 3-cycles, and since the 3-cycles generate \( A_n \), we must have \( N = A_n \). Second, prove that \( N \) must contain a 3-cycle. It is here that we need \( n \geq 5 \).

Suppose then that \( N \) contains a 3-cycle; without loss of generality \( N \) contains \((123)\). Now for any \( k > 3 \) the cycle \((32k)\) is an even permutation, so lies in \( A_n \) and, therefore,

\[
(32k)^{-1}(123)(32k) = (1k2)
\]

lies in \( N \). Hence \( N \) contains \((1k2)^2 = (12k)\) for all \( k \geq 3 \). We claim that \( A_n \) is generated by all 3-cycles of the form \((12k)\). If \( n = 3 \), then we are done. If \( n > 3 \), then for all \( a, b > 2 \) the permutation \((1a)(1b)\) is even, so lies in \( A_n \), and then \( A_n \) contains

\[
((1a)(1b))^{-1}(12k)(1a)(1b) = (abk)
\]

if \( k \neq a, b \). Since \( A_n \) is generated by all 3-cycles (Exercise 8.7), it follows that \( N = A_n \).

It remains to show that \( N \) must contain at least one 3-cycle. We do this by an analysis into cases.

1. Suppose that \( N \) contains an element \( x = abc \ldots \), where \( a, b, c, \ldots \) are disjoint cycles and

\[
a = (a_1 \ldots a_m) \quad (m \geq 4)
\]

Let \( t = (a_1a_2a_3) \). Then \( N \) contains \( t^{-1}xt \). Since \( t \) commutes with \( b, c, \ldots \) (disjointness of cycles) it follows that

\[
t^{-1}xt = (t^{-1}at)bc \ldots = z \quad (\text{say})
\]

so that \( N \) contains

\[
zx^{-1} = (a_1a_3a_m)
\]

which is a 3-cycle.
2. Now suppose \( N \) contains an element involving at least two 3-cycles. Without loss of generality \( N \) contains

\[ x = (123)(456)y \]

where \( y \) is a permutation fixing 1, 2, 3, 4, 5, 6. Let \( t = (234) \). Then \( N \) contains

\[ (t^{-1}xt)x^{-1} = (12436) \]

Then by case (1) \( N \) contains a 3-cycle.

3. Now suppose that \( N \) contains an element \( x \) of the form \( (ijk)p \), where \( p \) is a product of 2-cycles disjoint from each other and from \( (ijk) \). Then \( N \) contains \( x^2 = (ikj) \), which is a 3-cycle.

4. There remains the case when every element of \( N \) is a product of disjoint 2-cycles. (This actually occurs when \( n = 4 \), giving the four-group \( V \).) But as \( n \geq 5 \), we can assume that \( N \) contains

\[ x = (12)(34)p \]

where \( p \) fixes 1, 2, 3, 4. If we let \( t = (234) \), then \( N \) contains

\[ (t^{-1}xt)x^{-1} = (14)(23) \]

and if \( u = (145) \), \( N \) contains

\[ u^{-1}(t^{-1}xtx^{-1})u = (45)(23) \]

so that \( N \) contains

\[ (45)(23)(14)(23) = (145) \]

contradicting the assumption that every element of \( N \) is a product of disjoint 2-cycles.

Hence \( A_n \) is simple if \( n \geq 5 \).

In fact, \( A_5 \) is the smallest non-abelian simple group, a result that was first proved by Galois.

From this theorem we deduce Corollary 14.8.

**COROLLARY 14.8**

The symmetric group \( S_n \) of degree \( n \) is not soluble if \( n \geq 5 \).

**PROOF**  If \( S_n \) were soluble, then \( A_n \) would be soluble by Theorem 14.4, and simple by Theorem 14.7, hence of prime order by Theorem 14.6. But \( |A_n| = \frac{1}{2}(n!) \) is not prime if \( n \geq 5 \). \( \square \)
14.3 Cauchy's Theorem

We next prove Cauchy's Theorem: if a prime $p$ divides the order of a finite group, then the group has an element of order $p$. We begin by recalling several ideas from group theory.

**Definition 14.9** Elements $a$ and $b$ of a group $G$ are conjugate in $G$ if there exists $g \in G$ such that $a = g^{-1}bg$.

Conjugacy is an equivalence relation; the equivalence classes are the conjugacy classes of $G$.

If the conjugacy classes of $G$ are $C_1, \ldots, C_r$, then one of them, say $C_1$, contains only the identity element of $G$. Therefore, $|C_1| = 1$. Since the conjugacy classes form a partition of $G$ we have

$$|G| = 1 + |C_2| + \cdots + |C_r|$$

(14.2)

which is the class equation for $G$.

**Definition 14.10** If $G$ is a group and $x \in G$, then the centralizer $C_G(x)$ of $x$ in $G$ is the set of all $g \in G$ for which $xg = gx$. It is always a subgroup of $G$.

There is a useful connection between centralizers and conjugacy classes.

**Lemma 14.11**
If $G$ is a group and $x \in G$, then the number of elements in the conjugacy class of $x$ is the index of $C_G(x)$ in $G$.

**Proof** The equation $g^{-1}xg = h^{-1}xh$ holds if and only if $h_g^{-1}x = xh_g^{-1}$, which means that $h_g^{-1} \in C_G(x)$, that is, $h$ and $g$ lie in the same coset of $C_G(x)$ in $G$. The number of these cosets is the index of $C_G(x)$ in $G$, so the lemma is proved. □

**Corollary 14.12**
The number of elements in any conjugacy class of a finite group $G$ divides the order of $G$.

**Definition 14.13** The centre $Z(G)$ of a group $G$ is the set of all elements $x \in G$ such that $xg = gx$ for all $g \in G$.

The centre of $G$ is a normal subgroup of $G$. Many groups have a trivial centre, for example, $Z(S_3) = 1$. Abelian groups go to the other extreme and have $Z(G) = G$. 
**LEMMA 14.14**

If $A$ is a finite abelian group whose order is divisible by a prime $p$, then $A$ has an element of order $p$.

**PROOF** We use induction on $|A|$. If $|A|$ is prime the result follows. Otherwise take a proper subgroup $M$ of $A$ whose order $m$ is maximal. If $p$ divides $m$, we are home by induction, so we may assume that $p$ does not divide $m$. Let $b$ be in $A$ but not in $M$, and let $B$ be the cyclic subgroup generated by $b$. Then $MB$ is a subgroup of $A$, larger than $M$, so by maximality $A = MB$. From the First Isomorphism Theorem

$$|MB| = |M||B|/|M \cap B|$$

so that $p$ divides the order $r$ of $B$. Since $B$ is cyclic, the element $b^{r/p}$ has order $p$. The lemma follows.

From this result we can derive a more general theorem of Cauchy.

**THEOREM 14.15 (Cauchy’s Theorem)**

If a prime $p$ divides the order of a finite group $G$, then $G$ has an element of order $p$.

**PROOF** We prove the theorem by induction on the order $|G|$. The first few cases $|G| = 1, 2, 3$ are obvious. For the induction step, start with the class equation

$$|G| = 1 + |C_2| + \cdots + |C_r|$$

Since $p||G|$, we must have $p||C_j|$ for some $j \geq 2$. If $x \in C_j$, it follows that $p||C_G(x)|$, since $|C_j| = |G|/(C_G(x))$.

If $C_G(x) \neq G$, then by induction $C_G(x)$ contains an element of order $p$, and this element also belongs to $G$.

Otherwise, $C_G(x) = G$, which implies that $x \in Z(G)$, and by choice $x \neq 1$, so $Z(G) \neq 1$.

Either $p||Z(G)|$ or $p||Z(G)|$. In the first case the proof reduces to the abelian case, Lemma 14.14. In the second case, by induction there exists $x \in G$ such that the image $x \in G/Z(G)$ has order $p$. That is, $x^p \in Z(G)$ but $x \notin Z(G)$. Let $X$ be the cyclic group generated by $x$. Now $XZ(G)$ is abelian and has order divisible by $p$, so by Lemma 14.14 it has an element of order $p$, and again this element also belongs to $G$.

This completes the induction step, and with it the proof.

Cauchy’s Theorem does not work for composite divisors of $|G|$ (see Exercise 14.6).
Exercises

14.1 Show that the general dihedral group

$$D_{2n} = \langle a, b : a^n = b^2 = 1, b^{-1}ab = a^{-1} \rangle$$

is a soluble group. Here $a, b$ are generators and the equalities are relations between them.

14.2 Prove that $S_n$ is not soluble for $n \geq 5$, using only the simplicity of $A_5$.

14.3 Prove that a normal subgroup of a group is a union of conjugacy classes. Find the conjugacy classes of $A_5$, using the cycle type of the permutations, and hence show that $A_5$ is simple.

14.4 Prove that $S_n$ is generated by the 2-cycles $(12), \ldots, (1n)$.

14.5 If the point $(\alpha, \beta)$ is constructible by ruler and compasses from $(0, 0)$ and $(1, 0)$, show that the Galois groups of $Q(\alpha) : Q$ and $Q(\beta) : Q$ are soluble.

14.6 Show that $A_5$ has no subgroup of order 15, even though 15 divides its order.

14.7 Show that $S_n$ has a trivial centre if $n \geq 3$.

14.8 Find the conjugacy classes of the dihedral group $D_{2n}$ defined in Exercise 14.1. Work out the centralizers of selected elements, one from each conjugacy class, and check Lemma 14.11.

14.9 If $G$ is a group and $x, g \in G$, show that $C_G(g^{-1}xg) = g^{-1}C_G(x)g$.

14.10 Show that the relation "normal subgroup of" is not transitive. (Hint: Consider the subgroup $G \subseteq \Sigma \subseteq S_4$ generated by the element $(12)(34)$.)

14.11 There are (at least) two distinct ways to think about a group homomorphism. One is the definition as a structure-preserving mapping, the other is in terms of a quotient group by a normal subgroup. The relation between these is as follows. If $\phi : G \rightarrow H$ is a homomorphism, then

$$\ker(\phi) \triangleleft G \quad \text{and} \quad G/\ker(\phi) \cong \text{im}(\phi)$$

If $N \triangleleft G$, then there is a natural surjective homomorphism

$$\phi : G \rightarrow G/N \quad \text{with} \quad \ker(\phi) = N$$

Show that the first and second isomorphism theorems are the translations into quotient group language of two facts that are trivial in structure-preserving mapping language:
a. The restriction of a homomorphism to a subgroup is a homomorphism.
b. The composition of two homomorphisms is a homomorphism.

4.12* By counting the sizes of conjugacy classes, prove that the group of rotational symmetries of a regular icosahedron is simple. Show that it is isomorphic to $A_5$.

14.13 Mark the following true or false.
   a. The direct product of two soluble groups is soluble.
   b. Every simple soluble group is cyclic.
   c. Every cyclic group is simple.
   d. The symmetric group $S_n$ is simple if $n \geq 5$.
   e. Every conjugacy class of a group $G$ is a subgroup of $G$. 
Chapter 15

Solution by Radicals

The historical aspects of the problem of solving polynomial equations by radicals were discussed in the introduction. The objective of this chapter is to use the Galois correspondence to derive a condition that must be satisfied by any polynomial equation that is soluble by radicals, namely: the associated Galois group must be a soluble group. We then construct a quintic polynomial equation whose Galois group is not soluble, namely, the disarmingly straightforward-looking \( t^5 - 6t + 3 = 0 \), which shows that the quintic equation cannot be solved by radicals.

Solubility of the Galois group is also a sufficient condition for an equation to be soluble by radicals, but we defer this result to Chapter 18.

15.1 Radical Extensions

Some care is needed in formalizing the idea of solubility by radicals. We begin from the point of view of field extensions.

Informally, a radical extension is obtained by a sequence of adjunctions of \( n \)th roots, for various \( n \). For example, the following expression is radical:

\[
\sqrt[3]{11}\sqrt{\frac{7 + \sqrt{3}}{2}} + \sqrt[3]{1 + \sqrt[4]{4}}
\]  \hspace{1cm} (15.1)

To find an extension of \( \mathbb{Q} \) that contains this element we may adjoin, in turn, elements

\[
\alpha = \sqrt[3]{11} \hspace{0.5cm} \beta = \sqrt[3]{3} \hspace{0.5cm} \gamma = \sqrt[3]{(7 + \beta)/2} \hspace{0.5cm} \delta = \sqrt[4]{4} \hspace{0.5cm} \varepsilon = \sqrt[3]{1 + \delta}
\]

This suggests the following definition.

**Definition 15.1** An extension \( L : K \) in \( \mathbb{C} \) is radical if \( L = K(\alpha_1, \ldots, \alpha_m) \) where for each \( j = 1, \ldots, m \) there exists an integer \( n_j \) such that

\[
\alpha_j^{n_j} \in K(\alpha_1, \ldots, \alpha_{j-1}) \quad (j \geq 2)
\]

The elements \( \alpha_j \) form a radical sequence for \( L : K \). The radical degree of the radical \( \alpha_j \) is \( n_j \).
Figure 15.1: Galois thought he had solved the quintic . . . but changed his mind.

For example, the expression (15.1) is contained in a radical extension of the form $\mathbb{Q}(\alpha, \beta, \gamma, \delta, \varepsilon)$ of $\mathbb{Q}$, where $\alpha^3 = 11, \beta^2 = 3, \gamma^5 = (7 + \beta)/2, \delta^3 = 4, \varepsilon^4 = 1 + \delta$.

It is clear that any radical expression, in the sense of the introduction, is contained in some radical extension.

A polynomial should be considered soluble by radicals provided all of its zeros are radical expressions over the ground field.

**Definition 15.2** Let $f$ be a polynomial over a subfield $K$ of $\mathbb{C}$, and let $\Sigma$ be the splitting field for $f$ over $K$. We say that $f$ is soluble by radicals if there exists a field $M$ containing $\Sigma$ such that $M : K$ is a radical extension.

We emphasize that in the definition we do not require the splitting field extension $\Sigma : K$ to be radical. There is a good reason for this. We want everything in the splitting field $\Sigma$ to be expressible by radicals, but it is pointless to expect everything expressible by the same radicals to be inside the splitting field. If $M : K$ is radical and $L$ is an intermediate field, then $L : K$ need not be radical (see Exercise 15.7).

Note also that we require all zeros of $f$ to be expressible by radicals. It is possible for some zeros to be expressible by radicals, while others are not; simply take a product of two polynomials, one soluble by radicals and one not. However, if an irreducible polynomial $f$ has one zero expressible by radicals, then all the zeros must be so expressible, by a simple argument based on Corollary 5.13.

The main theorem of this chapter is Theorem 15.3.
THEOREM 15.3
If $K$ is a subfield of $\mathbb{C}$ and $K \subseteq L \subseteq M \subseteq \mathbb{C}$ where $M : K$ is a radical extension, then the Galois group of $L : K$ is soluble.

The otherwise curious word “soluble” for groups arises in this context: a soluble (by radicals) polynomial has a soluble Galois group (of its splitting field over the base field).

The proof of this result is not entirely straightforward, and we must spend some time on preliminaries.

LEMMA 15.4
If $L : K$ is a radical extension in $\mathbb{C}$ and $M$ is the normal closure of $L : K$, then $M : K$ is radical.

PROOF  Let $L = K(\alpha_1, \ldots, \alpha_r)$ with $\alpha_i^{n_i} \in K(\alpha_1, \ldots, \alpha_{i-1})$. Let $f_i$ be the minimal polynomial of $\alpha_i$ over $K$. Then $M \supseteq L$ is clearly the splitting field of $\prod_{i=1}^r f_i$. For every zero $\beta_{ij}$ of $f_i$ in $M$ there exists an isomorphism $\sigma : K(\alpha_i) \to K(\beta_{ij})$ by Corollary 5.13. By Proposition 11.4, $\sigma$ extends to a $K$-automorphism $\tau : M \to M$. Since $\alpha_i$ is radical over $K$, so is $\beta_{ij}$, and therefore so is $M$.

The next two lemmas show that certain Galois groups are abelian.

LEMMA 15.5
Let $K$ be a subfield of $\mathbb{C}$ and let $L$ be the splitting field for $t^p - 1$ over $K$, where $p$ is prime. Then the Galois group of $L : K$ is abelian.

We can say more: it is cyclic of order $p - 1$ (see Section 21.6).

PROOF  The derivative of $t^p - 1$ is $pt^{p-1}$, which is prime to $t^p - 1$, so by Lemma 9.13 the polynomial has no multiple zeros in $L$. Clearly, its zeros form a group under multiplication; this group has prime order $p$ since the zeros are distinct, so it is cyclic.

Let $\varepsilon$ be a generator of this group. Then $L = K(\varepsilon)$ so that any $K$-automorphism of $L$ is determined by its effect on $\varepsilon$. Further, $K$-automorphisms permute the zeros of $t^p - 1$. Hence any $K$-automorphism of $L$ is of the form

$$\alpha_j : \varepsilon \mapsto \varepsilon^j$$

and is uniquely determined by this condition. But then $\alpha_i \alpha_j$ and $\alpha_j \alpha_i$ both map $\varepsilon$ to $\varepsilon^{ij}$, so the Galois group is abelian.

LEMMA 15.6
Let $K$ be a subfield of $\mathbb{C}$ in which $t^n - 1$ splits. Let $a \in K$, and let $L$ be a splitting field for $t^n - a$ over $K$. Then the Galois group of $L : K$ is abelian.
PROOF  Let $\alpha$ be any zero of $t^n - a$. Since $t^n - 1$ splits in $K$, the general zero of $t^n - a$ is $\varepsilon\alpha$ where $\varepsilon$ is a zero of $t^n - 1$ in $K$. Since $L = K(\alpha)$, any $K$-automorphism of $L$ is determined by its effect on $\alpha$. Given two $K$-automorphisms

$$\phi : \alpha \mapsto \varepsilon\alpha \quad \psi : \alpha \mapsto \eta\alpha$$

where $\varepsilon$ and $\eta \in K$, then

$$\phi\psi(\alpha) = \varepsilon\eta\alpha = \varepsilon\eta\alpha = \psi\phi(\alpha)$$

As before, the Galois group is abelian.

Again, we can say more: the Galois group is cyclic of order $p$ (see Section 21.6). The main work in proving Theorem 15.3 is done in the next lemma.

**Lemma 15.7**

If $K$ is a subfield of $\mathbb{C}$ and $L : K$ is normal and radical, then $\Gamma(L : K)$ is soluble.

**Proof** Suppose that $L = K(\alpha_1, \ldots, \alpha_n)$ with $\alpha_j^{n_j} \in K(\alpha_1, \ldots, \alpha_{j-1})$. By Proposition 8.9 we may assume that $n_j$ is prime for all $j$. In particular there is a prime $p$ such that $\alpha_1^p \in K$.

We prove the result by induction on $n$, using the additional hypothesis that all $n_j$ are prime. The case $n = 0$ is trivial, which gets the induction started.

If $\alpha_1 \in K$, then $L = K(\alpha_2, \ldots, \alpha_n)$ and $\Gamma(L : K)$ is soluble by induction.

We may, therefore, assume that $\alpha_1 \notin K$. Let $f$ be the minimal polynomial of $\alpha_1$ over $K$. Since $L : K$ is normal, $f$ splits in $L$ because $K \subseteq \mathbb{C}$, $f$ has no repeated zeros. Since $\alpha_1 \notin K$, the degree of $f$ is at least 2. Let $\beta$ be a zero of $f$ different from $\alpha_1$, and put $\varepsilon = \alpha_1 / \beta$. Then $\varepsilon^p = 1$ and $\varepsilon \neq 1$. Thus $\varepsilon$ has order $p$ in the multiplicative group of $L$, so the elements $1, \varepsilon, \varepsilon^2, \ldots, \varepsilon^{p-1}$ are distinct $p$th roots of unity in $L$. Therefore, $t^p - 1$ splits in $L$.

Let $M \subseteq L$ be the splitting field for $t^p - 1$ over $K$, that is, let $M = K(\varepsilon)$. Consider the chain of subfields $K \subseteq M \subseteq M(\alpha_1) \subseteq L$. The strategy of the remainder of the proof is illustrated in the following diagram:

$$
\begin{array}{c}
L \\
\leftarrow \Gamma(L : M(\alpha_1)) \text{ soluble by induction} \\
M(\alpha_1) \\
\leftarrow \Gamma(M(\alpha_1) : M) \text{ abelian by Lemma 6} \\
M \\
\leftarrow \Gamma(M : K) \text{ abelian by Lemma 5} \\
K
\end{array}
$$
15.1 Radical Extensions

Observe that $L : K$ is finite and normal, hence so is $L : M$; therefore, Theorem 12.1 applies to $L : K$ and to $L : M$.

Since $t^p - 1$ splits in $M$ and $\alpha_1^p \in M$, the proof of Lemma 15.6 implies that $M(\alpha_1)$ is a splitting field for $t^p - \alpha_1^p$ over $M$. Thus $M(\alpha_1) : M$ is normal, and by Lemma 15.6 $\Gamma(M(\alpha_1) : M)$ is abelian. Apply Theorem 12.1 to $L : M$ to deduce that

$$\Gamma(M(\alpha_1) : M) \cong \Gamma(L : M) / \Gamma(L : M(\alpha_1))$$

Now

$$L = M(\alpha_1)(\alpha_2, \ldots, \alpha_n)$$

so that $L : M(\alpha_1)$ is a normal radical extension. By induction, $\Gamma(L : M(\alpha_1))$ is soluble. Hence by Theorem 14.4(3), $\Gamma(L : M)$ is soluble.

Since $M$ is the splitting field for $t^p - 1$ over $K$, the extension $M : K$ is normal. By Lemma 15.5, $\Gamma(M : K)$ is abelian. Theorem 12.1 applied to $L : K$ yields

$$\Gamma(M : K) \cong \Gamma(L : K) / \Gamma(L : M)$$

Now Theorem 15.4(3) shows that $\Gamma(L : K_0)$ is soluble, completing the induction step. 

We can now complete the proof of the main result.

PROOF OF THEOREM 15.3 Let $K_0$ be the fixed field of $\Gamma(L : K)$, and let $N : M$ be the normal closure of $M : K_0$. Then

$$K \subseteq K_0 \subseteq L \subseteq M \subseteq N$$

Since $M : K_0$ is radical, Lemma 15.4 implies that $N : K_0$ is a normal radical extension. By Lemma 15.7, $\Gamma(N : K_0)$ is soluble.

By Theorem 11.14, the extension $L : K_0$ is normal. By Theorem 12.1

$$\Gamma(L : K_0) \cong \Gamma(N : K_0) / \Gamma(N : L)$$

Theorem 15.4(2) implies that $\Gamma(L : K_0)$ is soluble. But $\Gamma(L : K) = \Gamma(L : K_0)$, so $\Gamma(L : K)$ is soluble.

The idea of this proof is simple: a radical extension is a series of extensions by $n$th roots. Such extensions have abelian Galois groups, so the Galois group of a radical extension is made up by fitting together a sequence of abelian groups. Unfortunately, there are technical problems in carrying out the proof; we need to throw in roots of unity, and we have to make various extensions normal before the Galois correspondence can be used. These obstacles are similar to those encountered by Abel and overcome by his Theorem on Natural Irrationalities in Section 8.8.

Now we translate back from fields to polynomials, and in doing so revert to Galois's original viewpoint.
DEFINITION 15.8 Let $f$ be a polynomial over a subfield $K$ of $\mathbb{C}$, with splitting field $\Sigma$ over $K$. The Galois group of $f$ over $K$ is the Galois group $\Gamma(\Sigma : K)$.

Let $G$ be the Galois group of a polynomial $f$ over $K$ and let $\partial f = n$. If $\alpha \in \Sigma$ is a zero of $f$, then $f(\alpha) = 0$, so for any $g \in G$

$$f(g(\alpha)) = g(f(\alpha)) = 0$$

Hence each element $g \in G$ induces a permutation $g'$ of the set of zeros of $f$ in $\Sigma$. Distinct elements of $G$ induce distinct permutations, since $\Sigma$ is generated by the zeros of $f$. It follows easily that the map $g \mapsto g'$ is a group monomorphism of $G$ into the group $S_n$ of all permutations of the zeros of $f$. In other words, we can think of $G$ as a group of permutations on the zeros of $f$. This, in effect, was how Galois thought of the Galois group, and for many years afterward the only groups considered by mathematicians were permutation groups and groups of transformations of variables. Arthur Cayley was the first to propose a definition for an abstract group, although it seems that the earliest satisfactory axiom system for groups was given by Leopold Kronecker in 1870 (Huntingdon, 1905).

We may restate Theorem 15.3 as:

THEOREM 15.9

Let $f$ be a polynomial over a subfield $K$ of $\mathbb{C}$. If $f$ is soluble by radicals, then the Galois group of $f$ over $K$ is soluble.

The converse also holds (see Theorem 18.19).

Thus, to find a polynomial not soluble by radicals, it suffices to find one whose Galois group is not soluble. There are two main ways of doing this. One is to look at the general polynomial of degree $n$, which we introduced in Section 8.7, but this approach has the disadvantage of not showing that there are specific polynomials with rational coefficients that are insoluble by radicals. The alternative approach, which we now pursue, is to exhibit a specific polynomial with rational coefficients whose Galois group is not soluble. Since Galois groups are hard to calculate, a little low cunning is necessary, together with some knowledge of the symmetric group.

15.2 An Insoluble Quintic

Watch carefully, there is nothing up my sleeve...

LEMMA 15.10

Let $p$ be a prime, and let $f$ be an irreducible polynomial of degree $p$ over $\mathbb{Q}$. Suppose that $f$ has precisely two nonreal zeros in $\mathbb{C}$. Then the Galois group of $f$ over $\mathbb{Q}$ is isomorphic to the symmetric group $S_p$. 
PROOF  By the Fundamental Theorem of Algebra, \( \mathbb{C} \) contains the splitting field \( \Sigma \) of \( f \). Let \( G \) be the Galois group of \( f \) over \( \mathbb{Q} \), considered as a permutation group on the zeros of \( f \). These are distinct by Proposition 9.14, so \( G \) is (isomorphic to) a subgroup of \( S_p \). When we construct the splitting field of \( f \) we first adjoin an element of degree \( p \), so \( [\Sigma : \mathbb{Q}] \) is divisible by \( p \). By Theorem 12.1(1), \( p \) divides the order of \( G \). By Cauchy’s Theorem 14.15, \( G \) has an element of order \( p \). But the only elements of \( S_p \) having order \( p \) are the \( p \)-cycles. Therefore, \( G \) contains a \( p \)-cycle.

Complex conjugation is a \( \mathbb{Q} \)-automorphism of \( \mathbb{C} \) and, therefore, induces a \( \mathbb{Q} \)-automorphism of \( \Sigma \). This leaves the \( p - 2 \) real zeros of \( f \) fixed, while transposing the two nonreal zeros. Therefore, \( G \) contains a 2-cycle.

By choice of notation for the zeros and, if necessary, taking a power of the \( p \)-cycle, we may assume that \( G \) contains the 2-cycle \( (12) \) and the \( p \)-cycle \( (12 \ldots p) \). We claim that these generate the whole of \( S_p \), which will complete the proof. To prove the claim, let \( c = (12 \ldots p) \), \( t = (12) \), and let \( G \) be the group generated by \( c \) and \( t \). Then \( G \) contains \( c^{-1}tc = (23) \), hence \( c^{-1}(23)c = (34), \ldots \) and hence all transpositions \((m, m + 1)\). Then \( G \) contains

\[
(12)(23)(12) = (13) \quad \text{and} \quad (13)(34)(13) = (14)
\]

and so on and, therefore, contains all transpositions \((1m)\). Finally, \( G \) contains all products \((1m)(1r)(1m) = (mr)\). But every element of \( S_n \) is a product of transpositions, so \( G = S_p \).

We can now exhibit a specific quintic polynomial over \( \mathbb{Q} \) that is not soluble by radicals.

THEOREM 15.11
The polynomial \( t^5 - 6t + 3 \) over \( \mathbb{Q} \) is not soluble by radicals.

PROOF  Let \( f(t) = t^5 - 6t + 3 \). By Eisenstein’s Criterion, \( f \) is irreducible over \( \mathbb{Q} \). We shall show that \( f \) has precisely three real zeros, each with multiplicity 1, and hence has two nonreal zeros. Since \( 5 \) is prime, by Lemma 15.10 the Galois group of \( f \) over \( \mathbb{Q} \) is \( S_5 \). By Corollary 14.8, \( S_5 \) is not soluble. By Theorem 15.9, \( f(t) = 0 \) is not soluble by radicals.

It remains to show that \( f \) has exactly three real zeros, each of multiplicity 1. Now \( f(-2) = -17 \), \( f(-1) = 8 \), \( f(0) = 3 \), \( f(1) = -2 \), and \( f(2) = 23 \). A rough sketch of the graph of \( y = f(x) \) looks like Figure 15.2. This certainly appears to give only three real zeros, but we must be rigorous. By Rolle’s theorem, the zeros of \( f \) are separated by zeros of \( Df \). Moreover, \( Df = 5t^4 - 6 \), which has two zeros at \( \pm \sqrt[6]{6} \). Clearly, \( f \) and \( Df \) are coprime, so \( f \) has no repeated zeros (this also follows by irreducibility) so \( f \) has at most three real zeros. But certainly \( f \) has at least three real zeros, since a continuous function defined on the real line cannot change sign except by passing through 0. Therefore, \( f \) has precisely three real zeros, and the result follows.
Figure 15.2: A quintic with three real zeros.

15.3 Other Methods

Of course, this is not the end of the story. There are more ways of killing a quintic than choking it with radicals. Having established the inadequacy of radicals for solving the problem, it is natural to look further afield.

First, some quintics are soluble by radicals. See Chapter 1 and Berndt, Spearman, and Williams (2002). What of the others, though?

On a mundane level, numerical methods can be used to find the zeros (real or complex) to any required degree of accuracy. In 1303 (see Joseph, 2000) the Chinese mathematician Chu Shih-chieh wrote about what was later called Horner's method in the West; there it was long credited to the otherwise unremarkable William George Horner, who discovered it in 1819. For hand calculations it is a useful practical method, but there are many others. The mathematical theory of such numerical methods can be far from mundane — but from the algebraic point of view it is nonilluminating.

Another way of solving the problem is to say, in effect, “What's so special about radicals?” Suppose for any real number $a$ we define the ultraradical of $a$ to be the real zero of $r^5 + r - a$. It was shown by G.B. Jerrard (see Kollros, 1949, p. 19) that the quintic equation can be solved by the use of radicals and ultraradicals (see King, 1996).

Instead of inventing new tools we can refashion existing ones. Charles Hermite made the remarkable discovery that the quintic equation can be solved in terms of “elliptic modular functions,” special functions of classical mathematics which arose in a quite different context, the integration of algebraic functions. The method is analogous to the trigonometric solution of the cubic equation (Exercise 1.6). In a triumph of mathematical unification, Klein (1913) succeeded in connecting the quintic equation, elliptic functions, and the rotation group of the regular icosahedron. The latter is isomorphic to the alternating group $A_5$, which we have seen plays a
key part in the theory of the quintic. Klein’s work helped to explain the unexpected appearance of elliptic functions in the theory of polynomial equations; these ideas were subsequently generalized by Henri Poincaré to cover polynomials of arbitrary degree.

Exercises

15.1 Find radical extensions of \( \mathbb{Q} \) containing the following elements of \( \mathbb{C} \), by exhibiting suitable radical sequences (see Definition 15.1):

a. \( (\sqrt{11} - \sqrt{23})/\sqrt{5} \)

b. \( (\sqrt{6} + 2\sqrt{5})/4 \)

c. \( (2\sqrt{5} - 4)/\sqrt{1 + \sqrt{99}} \)

15.2 What is the Galois group of \( t^p - 1 \) over \( \mathbb{Q} \) for prime \( p \)?

15.3 Show that the polynomials \( t^5 - 4t + 2, t^5 - 4t^2 + 2, t^5 - 6t^2 + 3 \), and \( t^7 - 10t^5 + 15t + 5 \) over \( \mathbb{Q} \) are not soluble by radicals.

15.4 Solve the sextic equation

\[
t^6 - t^5 + t^4 - t^3 + t^2 - t + 1 = 0
\]

satisfied by a primitive 14th root of unity, in terms of radicals. (Hint: Put \( u = t + 1/t \).)

15.5 Solve the sextic equation

\[
t^6 + 2t^5 - 5t^4 + 9t^3 - 5t^2 + 2t + 1 = 0
\]

by radicals. (Hint: Put \( u = t + 1/t \).

15.6 If \( L : K \) is a radical extension in \( \mathbb{C} \) and \( M \) is an intermediate field, show that \( M : K \) need not be radical.

15.7 If \( p \) is an irreducible polynomial over \( K \subseteq \mathbb{C} \) and at least one zero of \( p \) is expressible by radicals, prove that every zero of \( p \) is expressible by radicals.

15.8* If \( K \subseteq \mathbb{C} \) and \( \alpha^2 = a \in K, \beta^2 = b \in K \), and none of \( a, b, ab \) are squares in \( K \), prove that \( K(\alpha, \beta) : K \) has Galois group \( \mathbb{Z}_2 \times \mathbb{Z}_2 \).

15.9* Show that if \( N \) is an integer such that \( N > 1 \), and \( p \) is prime, then the quintic equation

\[
x^5 - Npx + p = 0
\]

cannot be solved by radicals.
15.10* Suppose that a quintic equation \( f(t) = 0 \) over \( \mathbb{Q} \) is irreducible, and has one real root and two complex conjugate pairs. Does an argument similar to that of Lemma 15.10 prove that the Galois group contains \( A_5 \)? If so, why? If not, why not?

15.11 Prove the Theorem on Natural Irrationalities using the Galois correspondence.

15.12 Mark the following true or false.

a. Every quartic equation over a subfield of \( \mathbb{C} \) can be solved by radicals.
b. Every radical extension is finite.
c. Every finite extension is radical.
d. The order of the Galois group of a polynomial of degree \( n \) divides \( n! \)
e. Any reducible quintic polynomial can be solved by radicals.
f. There exist quartics with Galois group \( S_4 \).
g. An irreducible polynomial of degree 11 with exactly two nonreal zeros has Galois group \( S_{11} \).
h. The normal closure of a radical extension is radical.
i. \( A_5 \) has 50 elements.
Chapter 16

Abstract Rings and Fields

Having seen how Galois Theory works in the context assumed by its inventor, we can
genitalize everything to a much broader context. Instead of subfields of \( \mathbb{C} \), we can con-
sider arbitrary fields. This step goes back to Weber in 1895, but first achieved promi-
nence in the work of Emil Artin in lectures of 1926, later published as Artin (1948).
With the increased generality, new phenomena arise, and these must be dealt with.

One such phenomenon relates to the Fundamental Theorem of Algebra, which does
not hold in an arbitrary field. We could get round this by constructing an analogue,
the algebraic closure of a field in which every polynomial splits into linear factors.
However, the machinery needed to prove the existence of an algebraic closure is
powerful enough to make the concept of an algebraic closure irrelevant anyway. So
we concentrate on developing that machinery, which centres on the abstract properties
of field extensions, especially finite ones.

A more significant problem is that a general field \( K \) need not contain \( \mathbb{Q} \) as a subfield.
The reason is that sums \( 1 + 1 + \cdots + 1 \) can behave in novel ways. In particular, such
a sum may be zero. If it is, then the number of summands must be a prime, and \( K \)
contains a subfield isomorphic to \( \mathbb{Z}_p \), the integers modulo \( p \). Such fields are said to
have characteristic \( p \), and they introduce significant complications into the theory. The
most important complication is that irreducible polynomials need not be separable;
that is, they may have multiple zeros. Separability is automatic for subfields of \( \mathbb{C} \), so
it has not been seen to play a major role up to this point. However, behind the scenes
it has been one of the two significant constraints that make Galois theory work, the
other being normality. From now on, separability has to be taken a lot more seriously,
and it has a substantial effect.

Rethinking the old results in the new context provides good revision and reinforce-
ment, and it explains where the general concepts come from. Nonetheless, if you
seriously work through the material and do not just accept that everything works, you
will come to appreciate that Bourbaki had a point.

16.1 Rings and Fields

Today's concepts of "ring" and "field" are the brainchildren of Dedekind, who
introduced them as a way of systematizing algebraic number theory; their influence
then spread and was reinforced by the growth of abstract algebra under the influence of
Weber, Hilbert, Emmy Noether, and Bartel Leenert van der Waerden. These concepts are motivated by the observation that the classical number systems \( \mathbb{Z}, \mathbb{Q}, \mathbb{R}, \) and \( \mathbb{C} \) enjoy a long list of useful algebraic properties. Specifically, \( \mathbb{Z} \) is a ring and the others are fields.

The formal definition of a ring is:

**DEFINITION 16.1** A ring \( R \) is a set equipped with two operations of addition (denoted \( a + b \)) and multiplication (denoted \( ab \)) satisfying the following axioms:

(A1) \( a + b = b + a \) for all \( a, b \in R \).

(A2) \( (a + b) + c = a + (b + c) \) for all \( a, b, c \in R \).

(A3) There exists \( 0 \in R \) such that \( 0 + a = a \) for all \( a \in R \).

(A4) Given \( a \in R \), there exists \( -a \in R \) such that \( a + (-a) = 0 \).

(M1) \( ab = ba \) for all \( a, b \in R \).

(M2) \( (ab)c = a(bc) \) for all \( a, b, c \in R \).

(M3) There exists \( 1 \in R \), with \( 1 \neq 0 \), such that \( 1a = a \) for all \( a \in R \).

(D) \( a(b + c) = ab + ac \) for all \( a, b, c \in R \).

When we say that addition and multiplication are operations on \( R \), we automatically imply that if \( a, b \in R \), then \( a + b, ab \in R \), so \( R \) is closed under each of these operations. Some axiom systems for rings include these conditions as explicit axioms.

Axioms (A1) and (M1) are the **commutative laws** for addition and multiplication, respectively. Axioms (A2) and (M2) are the **associative laws** for addition and multiplication, respectively. Axiom (D) is the **distributive law**. The element 0 is called the **additive identity** or zero element; the element 1 is called the **multiplicative identity** or unity element. The element \( -a \) is the **additive inverse** or **negative** of \( a \). The word "the" is justified here because 0 is unique, and for any given \( a \in F \) the inverse \( -a \) is unique. The condition \( 1 \neq 0 \) in (M3) excludes the trivial ring with one element.

The modern convention is that axioms (M1) and (M3) are optional for rings. Any ring that satisfies (M1) is said to be **commutative**, and any ring that satisfies (M3) is a ring with 1. However, in this book the phrase "commutative ring with 1" is shortened to "ring," because we do not require greater generality.

**Example 16.2**

1. The classical number systems \( \mathbb{Z}, \mathbb{Q}, \mathbb{R}, \mathbb{C} \) are all rings.

2. The set of natural numbers \( \mathbb{N} \) is not a ring, because axiom (A4) fails.

3. The set \( \mathbb{Z}[i] \) of all complex numbers of the form \( a + bi \), with \( a, b \in \mathbb{Z} \), is a ring.
4. The set of polynomials $\mathbb{Z}[t]$ over $\mathbb{Z}$ is a ring, as the usual name "ring of polynomials" indicates.

5. The set of polynomials $\mathbb{Z}[t_1, \ldots, t_n]$ in $n$ indeterminates over $\mathbb{Z}$ is a ring.

6. If $n$ is any integer, the set $\mathbb{Z}_n$ of integers modulo $n$ is a ring.

If $R$ is a ring, then we can define subtraction by

$$a - b = a + (-b) \quad a, b \in R$$

The axioms ensure that all of the usual algebraic rules of manipulation, except those for division, hold in any ring.

One extra axiom is required for a field.

**Definition 16.3** A field is a ring $F$ satisfying the extra axiom.

(M4) Given $a \in F$, with $a \neq 0$, there exists $a^{-1} \in F$ such that $aa^{-1} = 1$.

We call $a^{-1}$ the multiplicative inverse of $a \neq 0$. This inverse is also unique. If $F$ is a field, then we can define division by

$$a/b = ab^{-1} \quad a, b \in F, b \neq 0$$

The axioms ensure that all the usual algebraic rules of manipulation, including those for division, hold in any field.

**Example 16.4**

1. The classical number systems $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$ are all fields.

2. The set of integers $\mathbb{Z}$ is not a field, because axiom (M4) fails.

3. The set $\mathbb{Q}[i]$ of all complex numbers of the form $a + bi$, with $a, b \in \mathbb{Q}$, is a field.

4. The set of polynomials $\mathbb{Q}[t]$ over $\mathbb{Q}$ is not a field, because axiom (M4) fails.

5. The set of rational functions $\mathbb{Q}[t]$ over $\mathbb{Q}$ is a field.

6. The set of rational functions $\mathbb{Q}(t_1, \ldots, t_n)$ in $n$ indeterminates over $\mathbb{Q}$ is a field.

7. The set $\mathbb{Z}_2$ of integers modulo 2 is a field. The multiplicative inverses of the only nonzero element 1 is $1^{-1} = 1$. In this field, $1 + 1 = 0$. So $1 + 1 \neq 0$ does not count as one of the usual laws of algebra. Note that it involves an inequality; the statement $1 + 1 = 2$ is true in $\mathbb{Z}_2$. What is not true is that $2 \neq 0$.

8. The set $\mathbb{Z}_6$ of integers modulo 6 is not a field, because axiom (M4) fails. In fact, the elements 2, 3, 4 do not have multiplicative inverses. Indeed, $2 \cdot 3 = 0$ but $2, 3 \neq 0$. 

a phenomenon that cannot occur in a field: if \( F \) is a field, and \( a, b \neq 0 \) in \( F \) but \( ab = 0 \), then \( a = abb^{-1} = 0b^{-1} = 0 \), a contradiction.

9. The set \( \mathbb{Z}_5 \) of integers modulo 5 is a field. The multiplicative inverses of the nonzero elements are \( 1^{-1} = 1, 2^{-1} = 3, 3^{-1} = 2, 4^{-1} = 4 \). In this field, \( 1 + 1 + 1 + 1 + 1 = 0 \).

10. The set \( \mathbb{Z}_1 \) of integers modulo 1 is not a field. It consists of the single element 0, and so violates (M3) which states that \( 1 \neq 0 \). This is a sensible convention since 1 is not prime.

The fields \( \mathbb{Z}_2 \) and \( \mathbb{Z}_5 \), or more generally \( \mathbb{Z}_p \) where \( p \) is prime (see Theorem 7 below), are prototypes for an entirely new kind of field, with unusual properties. For example, the formula for solving quadratic equations fails spectacularly over \( \mathbb{Z}_2 \). Suppose that we want to solve

\[
t^2 + at + b = 0
\]

where \( a, b \in \mathbb{Z}_2 \). Completing the square involves rewriting the equation in terms of \( (t + a/2) \). But \( a/2 = a/0 \) makes no sense. The standard quadratic formula involves division by 2 and also makes no sense. Nevertheless, many choices of \( a, b \) here lead to soluble equations:

\[
t^2 = 0 \quad \text{has solution } t = 0
\]
\[
t^2 + 1 = 0 \quad \text{has solution } t = 1
\]
\[
t^2 + t = 0 \quad \text{has solutions } t = 0, 1
\]
\[
t^2 + t + 1 = 0 \quad \text{has no solution}
\]

### 16.2 General Properties of Rings and Fields

We briefly develop some of the basic properties of rings and fields, with emphasis on structural features that will allow us to construct examples of fields. Among these features are the presence or absence of “divisors of zero” (like \( 2, 3 \in \mathbb{Z}_6 \)), leading to the concept of an integral domain, and the notion of an ideal in a ring, leading to quotient rings and a general construction for interesting fields. Most readers will have encountered these ideas before; if not, it may be a good idea to find an introductory textbook and work through the first two or three chapters. For example, Fraleigh (1989) and Sharpe (1987) cover the relevant material.

**DEFINITION 16.5**

1. A subring of a ring \( R \) is a nonempty subset \( S \) of \( R \) such that if \( a, b \in S \), then \( a + b \in S, a - b \in S, \text{ and } ab \in S \).
2. A subfield of a field $F$ is a subset $S$ of $F$ containing the elements 0 and 1, such that if $a, b \in S$, then $a + b, a - b, ab \in S$, and further if $a \neq 0$, then $a^{-1} \in S$.

3. An ideal of a ring $R$ is a subring $I$ such that if $i \in I$ and $r \in R$, then $ir$ and $ri$ lie in $I$.

Thus $\mathbb{Z}$ is a subring of $\mathbb{Q}$, and $\mathbb{R}$ is a subfield of $\mathbb{C}$, while the set $2\mathbb{Z}$ of even integers is an ideal of $\mathbb{Z}$.

If $R, S$ are rings, then a ring homomorphism $\phi : R \to S$ is a map that satisfies two conditions:

$$
\phi(r + s) = \phi(r) + \phi(s) \quad \phi(rs) = \phi(r)\phi(s) \quad \text{for all } r \in R, s \in S
$$

The kernel $\ker \phi$ of $\phi$ is $\{r : \phi(r) = 0\}$. It is an ideal of $R$. An isomorphism is a homomorphism that is one-to-one and onto; a monomorphism is a homomorphism that is one-to-one. A homomorphism is a monomorphism if and only if its kernel is zero.

The most important property of an ideal is the possibility of working modulo that ideal or, more abstractly, constructing the quotient ring by that ideal. Specifically, if $I$ is an ideal of the ring $R$, then the quotient ring $R/I$ consists of the cosets $I + s$ of $I$ in $R$ (considering $R$ as a group under addition). The operations in the quotient ring are:

$$(I + r) + (I + s) = I + (r + s)$$
$$(I + r)(I + s) = I + (rs)$$

where $r, s \in R$ and $I + r$ is the coset $\{i + r : i \in I\}$.

**Example 16.6**

1. Let $n\mathbb{Z}$ be the set of integers divisible by a fixed integer $n$. This is an ideal of $\mathbb{Z}$, and the quotient ring $\mathbb{Z}/n\mathbb{Z}$ is the ring of integers modulo $n$, that is, $\mathbb{Z}_n$.

2. Let $R = K[t]$ where $K$ is a subfield of $\mathbb{C}$, and let $m(t)$ be an irreducible polynomial over $K$. Define $I = \langle m(t) \rangle$ to be the set of all multiples of $m(t)$. Then $I$ is an ideal, and $R/I$ is what we previously denoted by $K[t]/\langle m \rangle$ in Chapter 5. This quotient is a field.

3. We can perform the same construction as in Example 16.6(2) above, without taking $m$ to be irreducible. We still get a quotient ring, but if $m$ is reducible the quotient is no longer a field.

There is a natural ring homomorphism $\phi : R \to R/I$, defined by $\phi(r) = I + r$. Its kernel is $R$.

We shall need the following property of $\mathbb{Z}_n$, which explains the differences we found among $\mathbb{Z}_2, \mathbb{Z}_3,$ and $\mathbb{Z}_6$. 

THEOREM 16.7
The ring \( \mathbb{Z}_n \) is a field if and only if \( n \) is a prime number.

PROOF First suppose that \( n \) is not prime. If \( n = 1 \), then \( \mathbb{Z}_n = \mathbb{Z}/\mathbb{Z} \), which has only one element and so cannot be a field. If \( n > 1 \), then \( n = rs \) where \( r \) and \( s \) are integers less than \( n \). Putting \( I = n\mathbb{Z} \),

\[
(I + r)(I + s) = I + rs = I
\]

But \( I \) is the zero element of \( \mathbb{Z}/I \), while \( I + r \) and \( I + s \) are nonzero. Since in a field the product of two nonzero elements is nonzero, \( \mathbb{Z}/I \) cannot be a field.

Now suppose that \( n \) is prime. Let \( I + r \) be a nonzero element of \( \mathbb{Z}/I \). Since \( r \) and \( n \) are coprime, then by standard properties of \( \mathbb{Z} \) there exist integers \( a \) and \( b \) such that \( ar + bn = 1 \). Therefore,

\[
(I + a)(I + r) = (I + 1) - (I + n)(I + b) = I + 1
\]

and similarly,

\[
(I + r)(I + a) = I + 1
\]

Since \( I + 1 \) is the identity element of \( \mathbb{Z}/I \), we have found a multiplicative inverse for the given element \( I + r \). Thus every nonzero element of \( \mathbb{Z}/I \) has an inverse, so that \( \mathbb{Z}_n = \mathbb{Z}/I \) is a field. \( \square \)

From now on when dealing with \( \mathbb{Z}_n \), we revert to the usual convention and write the elements as \( 0, 1, 2, \ldots, n - 1 \) rather than \( I, I + 1, I + 2, \ldots, I + n - 1 \).

---

16.3 Polynomials Over General Rings

We now introduce polynomials with coefficients in a given ring. The main point to bear in mind is that identifying polynomials with functions, as we cheerfully did for coefficients in \( \mathbb{C} \), is no longer a good idea.

Why not? Consider the ring \( \mathbb{Z}_2 \). Suppose that \( f(t) = t^2 + 1 \), \( g(t) = t^4 + 1 \). There are numerous reasons to want these to be different polynomials, the most obvious being that they have different coefficients. But if we interpret them as functions from \( \mathbb{Z}_2 \) to itself, we find that \( f(0) = 1 = g(0) \) and \( f(1) = 0 = g(1) \). As functions, \( f \) and \( g \) are equal.

It turns out that a problem arises here because the ring is finite. Since finite rings (especially finite fields) are important, we need a definition of polynomials that does not rely on interpreting them as functions.

Let \( R \) be a ring. We define a polynomial over \( R \) in the indeterminate \( t \) to be an expression

\[
r_0 + r_1 t + \cdots + r_n t^n
\]
where \( r_0, \ldots, r_n \in R \), \( 0 \leq n \in \mathbb{Z} \), and \( t \) is undefined. Again, for set-theoretic purity we can replace such an expression by the sequence \( (r_0, \ldots, r_n) \), as in Exercise 2.2. The elements \( r_0, \ldots, r_n \) are the coefficients of the polynomial.

Two polynomials are defined to be equal if and only if the corresponding coefficients are equal (with the understanding that powers of \( t \) not occurring in the polynomial may be taken to have zero coefficient). The sum and the product of two polynomials are defined using the same formulas as in Section 2.1, but now the \( r_i \) belong to a general ring. It is straightforward to check that the set of all polynomials over \( R \) in the indeterminate \( t \) is a ring — the ring of polynomials over \( R \) in the indeterminate \( t \). As before, we denote this by the symbol \( R[t] \). We can also define polynomials in several indeterminates \( t_1, t_2, \ldots \) and obtain the polynomial ring \( R[t_1, t_2, \ldots] \). Again, each polynomial \( f \in R[t] \) defines a function from \( R \) to \( R \). We use the same symbol, \( f \), to denote this function. If \( f(t) = \sum r_i t^i \), then \( f(\alpha) = \sum r_i \alpha^i \), for \( \alpha \in R \). We reiterate that two distinct polynomials over \( R \) may give rise to the same function on \( R \).

Proposition 2.3 is still true when \( R = \mathbb{R}, \mathbb{Q}, \) or \( \mathbb{Z} \), because the proof uses only properties of the integers \( 0, 1, \ldots, n \). And the definition of “degree” applies without change, as does the proof of Proposition 2.2.

---

16.4 The Characteristic of a Field

In Proposition 4.4 we observed that every subfield of \( \mathbb{C} \) must contain \( \mathbb{Q} \). The main step in the proof was that the subfield contains all elements \( 1 + 1 + \cdots + 1 \); that is, it contains \( \mathbb{N} \), hence \( \mathbb{Z} \), hence \( \mathbb{Q} \).

The same idea nearly works for any field. However, a finite field such as \( \mathbb{Z}_5 \) cannot contain \( \mathbb{Q} \), or even anything isomorphic to \( \mathbb{Q} \), because \( \mathbb{Q} \) is infinite. How does the proof fail? As we have already seen, in \( \mathbb{Z}_5 \) the equation \( 1 + 1 + 1 + 1 + 1 = 0 \) holds. So we can build up a unique smallest subfield just as before — but now it need not be isomorphic to \( \mathbb{Q} \).

Pursuing this line of thought leads to:

**Definition 16.8** The prime subfield of a field \( K \) is the intersection of all subfields of \( K \).

It is easy to see that the intersection of any collection of subfields of \( K \) is a subfield (the intersection is not empty since every subfield contains 0 and 1) and, therefore, the prime subfield of \( K \) is the unique smallest subfield of \( K \). The fields \( \mathbb{Q} \) and \( \mathbb{Z}_p \) \((p \text{ prime})\) have no proper subfields, so are equal to their prime subfields. The next theorem shows that these are the only fields that can occur as prime subfields.

**Theorem 16.9**
Every prime subfield is isomorphic either to the field \( \mathbb{Q} \) of rationals or the field \( \mathbb{Z}_p \) of integers modulo a prime number \( p \).
**PROOF** Let \( K \) be a field, with \( P \) its prime subfield. Then \( P \) contains 0 and 1 and, therefore, contains the elements \( n^* \) \( (n \in \mathbb{Z}) \) defined by

\[
  n^* = \begin{cases} 
    1 + 1 + \cdots + 1 \text{ (\( n \) times)} & \text{if } n > 0 \\
    0 & \text{if } n = 0 \\
    -(\neg n)^* & \text{if } n < 0
  \end{cases}
\]

A short calculation using the distributive law (D) and induction shows that the map \( \cdot^* : \mathbb{Z} \to P \) so defined is a ring homomorphism. Two distinct cases arise.

**Case 1.** \( n^* = 0 \) for some \( n \neq 0 \). Since also \( -(\neg n)^* = 0 \), there exists a smallest positive integer \( p \) such that \( p^* = 0 \). If \( p \) is composite, say \( p = rs \) where \( r \) and \( s \) are smaller positive integers, then \( r^*s^* = p^* = 0 \), so either \( r^* = 0 \) or \( s^* = 0 \), contrary to the definition of \( p \). Therefore, \( p \) is prime. The elements \( n^* \) form a ring isomorphic to \( \mathbb{Z}_p \), which is a field by Theorem 16.7. This must be the whole of \( P \), since \( P \) is the smallest subfield of \( K \).

**Case 2.** \( n^* \neq 0 \) if \( n \neq 0 \). Then \( P \) must contain all the elements \( m^*/n^* \) where \( m, n \) are integers and \( n \neq 0 \). These form a subfield isomorphic to \( \mathbb{Q} \) (by the map which sends \( m^*/n^* \) to \( m/n \)) which is necessarily the whole of \( P \).

The distinction among possible prime subfields is summed up by:

**DEFINITION 16.10** The characteristic of a field \( K \) is 0 if the prime subfield of \( K \) is isomorphic to \( \mathbb{Q} \), and \( p \) if the prime subfield of \( K \) is isomorphic to \( \mathbb{Z}_p \).

For example, the fields \( \mathbb{Q}, \mathbb{R}, \mathbb{C} \) all have characteristic zero, since in each case the prime subfield is \( \mathbb{Q} \). The field \( \mathbb{Z}_p \) \((p \text{ prime})\) has characteristic \( p \). We shall see later that there are other fields of characteristic \( p \); for an example, see Exercise 16.2.

The elements \( n^* \) defined in the proof of Theorem 16.9 are of considerable importance in what follows. It is conventional to omit the asterisk and write \( n \) instead of \( n^* \). This abuse of notation will cause no confusion as long as it is understood that \( n \) may be zero in the field without being zero as an integer. Thus, in \( \mathbb{Z}_5 \), we have \( 10 = 0 \) and \( 2 = 7 = -3 \). This difficulty does not arise in fields of characteristic zero.

With this convention, a product \( nk(n \in \mathbb{Z}, k \in K) \) makes sense, and

\[
nk = \pm (k + \cdots + k)
\]

**LEMMA 16.11**

If \( K \) is a subfield of \( L \), then \( K \) and \( L \) have the same characteristic.

**PROOF** In fact, \( K \) and \( L \) have the same prime subfield.

**LEMMA 16.12**

If \( k \) is a nonzero element of the field \( K \), and if \( n \) is an integer such that \( nk = 0 \), then \( n \) is a multiple of the characteristic of \( K \).
PROOF We must have \( n = 0 \) in \( K \), that is, in old notation, \( n^* = 0 \). If the characteristic is 0, then this implies that \( n = 0 \) is an integer. If the characteristic is \( p > 0 \), then it implies that \( n \) is a multiple of \( p \).

16.5 Integral Domains

The ring \( \mathbb{Z} \) has an important property, which is shared by many of the other rings that we shall be studying: if \( mn = 0 \) where \( m, n \) are integers, then \( m = 0 \) or \( n = 0 \). We abstract this property as:

**Definition 16.13** A ring \( R \) is an integral domain if for \( r, s \in R \), implies that \( r = 0 \) or \( s = 0 \).

We often express this condition as “\( D \) has no zero-divisors,” where a zero-divisor is a nonzero element \( a \in D \) for which there exists a nonzero element \( b \in D \) such that \( ab = 0 \).

**Example 16.14**

1. The integers \( \mathbb{Z} \) form an integral domain.

2. Any field is an integral domain. Suppose \( K \) is a field and \( rs = 0 \). Then either \( s = 0 \), or \( r = rss^{-1} = 0s^{-1} = 0 \).

3. The ring \( \mathbb{Z}_6 \) is not an integral domain. As observed earlier, in this ring \( 2.3 = 0 \) but \( 2, 3 \neq 0 \).

4. The polynomial ring \( \mathbb{Z}[t] \) is an integral domain. If \( f(t)g(t) = 0 \) as polynomials, but \( f(t), g(t) \neq 0 \), then we can find an element \( x \in \mathbb{Z} \) such that \( f(x) \neq 0, g(x) \neq 0 \). (Just choose \( x \) different from the finite set of zeros of \( f \) together with zeros of \( g \).) But then \( f(x)g(x) \neq 0 \), a contradiction.

It turns out that a ring is an integral domain if and only if it is (isomorphic to) a subring of some field. To understand how this comes about, we analyse when it is possible to embed a ring \( R \) in a field — that is, find a field containing a subring isomorphic to \( R \). Thus \( \mathbb{Z} \) can be embedded in \( \mathbb{Q} \). This particular example has the property that every element of \( \mathbb{Q} \) is a fraction whose numerator and denominator lie in \( \mathbb{Z} \). We wish to generalize this situation.

**Definition 16.15** A field of fractions of the ring \( R \) is a field \( K \) containing a subring \( R' \) isomorphic to \( R \), such that every element of \( K \) can be expressed in the form \( r/s \) for \( r, s \in R' \), where \( s \neq 0 \).
To see how to construct a field of fractions for $R$, we analyse how $\mathbb{Z}$ is embedded in $\mathbb{Q}$. We can think of a rational number, written as a fraction $r/s$, as an ordered pair $(r, s)$ of integers. However, the same rational number corresponds to many distinct fractions: for instance, $\frac{2}{3} = \frac{4}{6} = \frac{10}{15}$ and so on. Therefore, the pairs $(2, 3), (4, 6),$ and $(10, 15)$ must be treated as if they are the same. The way to achieve this is to define an equivalence relation that makes them equivalent to each other. In general, $(r, s)$ represents the same rational as $(t, u)$ if and only if $r/s = t/u$; that is, $ru = st$. In this form the condition involves only the arithmetic of $\mathbb{Z}$. By generalizing these ideas we obtain:

**THEOREM 16.16**
Every integral domain possesses a field of fractions.

**PROOF** Let $R$ be an integral domain, and let $S$ be the set of all ordered pairs $(r, s)$ where $r$ and $s$ lie in $R$ and $s \neq 0$. Define a relation $\sim$ on $S$ by

$$(r, s) \sim (t, u) \iff ru = st$$

It is easy to verify that $\sim$ is an equivalence relation; we denote the equivalence class of $(r, s)$ by $[r, s]$. The set $F$ of equivalence classes will provide the required field of fractions. First we define the operations on $F$ by

$$[r, s] + [t, u] = [ru + is, su]$$

$$[r, s][t, u] = [rt, su]$$

Then we perform a long series of computations to show that $F$ has all the required properties. Since these computations are routine we shall not perform them here, but if you've never seen them, you should check them for yourself (see Exercise 16.3). What you have to prove is:

1. The operations are well defined. That is to say, if $(r, s) \sim (r', s')$ and $(t, u) \sim (t', u')$, then

$$[r, s] + [t, u] = [r', s'] + [t', u']$$

$$[r, s][t, u] = [r', s'][t', u']$$

2. They are operations on $F$ (this is where we need to know that $R$ is an integral domain).

3. $F$ is a field.

4. The map $R \to F$ that sends $r \to [r, 1]$ is a monomorphism.

5. $[r, s] = [r, 1]/[s, 1]$. 

\[\top\]
It can be shown (Exercise 16.4) that for a given integral domain $R$, all fields of fractions are isomorphic. We can, therefore, refer to the field constructed above as the field of fractions of $R$. It is customary to identify an element $r \in R$ with its image $[r, 1]$ in $F$, whereupon $[r, s] = r/s$.

A short calculation reveals a useful property: whenever $R$ is an integral domain, so is $R[t]$.

**Lemma 16.17**

If $R$ is an integral domain and $t$ is an indeterminate, then $R[t]$ is an integral domain.

**Proof** Suppose that

$$f = f_0 + f_1 t + \ldots + f_n t^n \quad g = g_0 + g_1 t + \ldots + g_m t^m$$

where $f_n \neq 0 \neq g_m$ and all the coefficients lie in $R$. The coefficient of $t^{m+n}$ in $fg$ is $f_n g_m$, which is nonzero since $R$ is an integral domain. Thus if $f, g$ are nonzero, then $fg$ is nonzero. This implies that $R[t]$ is an integral domain, as claimed. ☐

**Corollary 16.18**

If $F$ is a field, then the polynomial ring $F[t_1, \ldots, t_n]$ in $n$ indeterminates is an integral domain for any $n$.

**Proof** Write $F[t_1, \ldots, t_n] = F[t_1][t_2, \ldots, t_n]$ and use induction. ☐

Proposition 2.2 applies to polynomials over any integral domain.

Theorem 16.16 implies that when $R$ is an integral domain, $R[t]$ has a field of fractions. We call this the field of rational expressions in $t$ over $R$ and denote it by $R(t)$. Its elements are of the form $p(t)/q(t)$ where $p$ and $q$ are polynomials and $q$ is not the zero polynomial. Similarly, $R[t_1, \ldots, t_n]$ has a field of fractions $R(t_1, \ldots, t_n)$. Rational expressions can be considered as fractions $p(t)/q(t)$, where $p, q \in R[t]$ and $q$ is not the zero polynomial. If we add two such fractions together, or multiply them, the result is another such fraction. In fact, by the usual rules of algebra,

$$\frac{p(t)}{q(t)} \frac{r(t)}{s(t)} = \frac{p(t)r(t)}{q(t)s(t)}$$

$$\frac{p(t)}{q(t)} + \frac{r(t)}{s(t)} = \frac{p(t)s(t) + q(t)r(t)}{q(t)s(t)}$$

We can also divide and subtract such expressions:

$$\frac{p(t)}{q(t)} \div \frac{r(t)}{s(t)} = \frac{p(t)s(t)}{q(t)r(t)}$$

$$\frac{p(t)}{q(t)} - \frac{r(t)}{s(t)} = \frac{p(t)s(t) - q(t)r(t)}{q(t)s(t)}$$

where in the first equation, we assume $r(t)$ is not the zero polynomial.
The Division Algorithm and the Euclidean Algorithm work for polynomials over any field, without change. Therefore, the entire theory of factorization of polynomials, including irreducibles, works for polynomials in \( K[t] \) whose coefficients lie in any field \( K \).

---

**Exercises**

16.1 Show that \( 15\mathbb{Z} \) is an ideal of \( 5\mathbb{Z} \), and that \( 5\mathbb{Z}/15\mathbb{Z} \) is isomorphic to \( \mathbb{Z}_3 \).

16.2 Are the rings \( \mathbb{Z} \) and \( 2\mathbb{Z} \) isomorphic?

16.3 Write out addition and multiplication tables for \( \mathbb{Z}_6, \mathbb{Z}_7, \) and \( \mathbb{Z}_8 \). Which of these rings are integral domains? Which are fields?

16.4 Define a prime field to be a field with no proper subfields. Show that the prime fields (up to isomorphism) are precisely \( \mathbb{Q} \) and \( \mathbb{Z}_p \) (\( p \) prime).

16.5 Find the prime subfield of \( \mathbb{Q}, \mathbb{R}, \mathbb{C}, \mathbb{Q}(t), \mathbb{R}(t), \mathbb{C}(t), \mathbb{Z}_5(t), \mathbb{Z}_{17}(t_1, t_2) \).

16.6 Show that the following tables define a field.

<table>
<thead>
<tr>
<th>+</th>
<th>0</th>
<th>1</th>
<th>( \alpha )</th>
<th>( \beta )</th>
</tr>
</thead>
<tbody>

Find its prime subfield \( P \).

16.7 Prove properties 1 to 5 asserted above in the construction of the field of fractions of an integral domain in Theorem 16.16.

16.8 Let \( D \) be an integral domain with a field of fractions \( F \). Let \( K \) be any field. Prove that any monomorphism \( \phi : D \rightarrow K \) has a unique extension to a monomorphism \( \psi : F \rightarrow K \) defined by

\[
\psi(a/b) = \phi(a)/\phi(b)
\]

for \( a, b \in D \). By considering the case where \( K \) is another field of fractions for \( D \) and \( \phi \) is the inclusion map show that fields of fractions are unique up to isomorphism.
16.9 Let $K = \mathbb{Z}_2$. Describe the subfields of $K(t)$ of the form:

a. $K(t^2)$

b. $K(t + 1)$

c. $K(t^5)$

d. $K(t^2 + 1)$

16.10 Does the condition $\partial(f + g) \leq \max(\partial f, \partial g)$ hold for polynomials $f, g$ over a general ring?

By considering the polynomials $3t$ and $2t$ over $\mathbb{Z}_6$ show that the equality $\partial(fg) = \partial f + \partial g$ fails for polynomials over a general ring $R$. What if $R$ is an integral domain?

16.11 Mark the following true or false:

a. Every integral domain is a field.

b. Every field is an integral domain.

c. If $F$ is a field, then $F[t]$ is a field.

d. If $F$ is a field, then $F(t)$ is a field.

e. $\mathbb{Z}(t)$ is a field.
Chapter 17

Abstract Field Extensions

We have now sorted out what we mean by a field, and equipped ourselves with several theoretical ways to construct fields starting from rings. We now attack the general structure of an abstract field extension. Our previous work with subfields of \( \mathbb{C} \) paves the way, and most of our effort goes into making minor changes to the terminology and checking carefully that the underlying ideas generalize in the obvious manner.

We begin by extending the classification of simple extensions to general fields. Having done that, we assure ourselves that the theory of normal extensions, including their relation to splitting fields, carries over to the general case. We deal with the new issue of separability. Our main result is that the Galois correspondence can be set up for any finite separable normal extension and then has exactly the same properties that we have already proved over \( \mathbb{C} \).

**Convention on Generalizations.** Quite a lot of this chapter consists of routine verification that theorems previously stated and proved for subfields or subrings of \( \mathbb{C} \) remain valid for general rings and fields — and have essentially the same proofs. As a standing convention, we refer to "Lemma X.Y (generalized)" to mean the generalization to an arbitrary ring or field of Lemma X.Y; usually we do not restate Lemma X.Y in its new form. In cases where the proof requires a new method or extra hypotheses, we will be more specific. Moreover, some of the most important theorems will be restated explicitly.

17.1 Minimal Polynomials

**Definition 17.1** A field extension is a monomorphism \( \nu : K \rightarrow L \), where \( K, L \) are fields.

Usually we identify \( K \) with its image \( \nu(K) \), and in this case \( K \) becomes a subfield of \( L \).

We write \( L : K \) for an extension where \( K \) is a subfield of \( L \).

We can define the degree \([L : K]\) of the extension \( L : K \) exactly as in Chapter 6. Namely, consider \( L \) as a vector space over \( K \) and take its dimension. The Tower Law remains valid and has exactly the same proof.
In Chapter 16 we observed that all of the usual properties of factorization of polynomials over \( \mathbb{C} \) carry over, without change, to general polynomials. (Even Gauss's Lemma and Eisenstein's Criterion can be generalized to polynomials over suitable rings, but we do not discuss such generalizations here.) Specifically, the definitions of reducible and irreducible polynomials, uniqueness of factorization into irreducibles, and the concept of an hcf carry over to the general case. Moreover, if \( K \) is a field and \( h \in K[t] \) is an hcf of \( f, g \in K[t] \), then there exist \( a, b \in K[t] \) such that \( h = af + bg \). As before, we say that a polynomial is monic if its term of highest degree has coefficient 1.

If \( L : K \) is a field extension and \( \alpha \in L \), the same dichotomy arises: either \( \alpha \) is a zero of some polynomial \( f \in K[t] \), or it is not. In the first case, \( \alpha \) is algebraic over \( K \); in the second case, \( \alpha \) is transcendental over \( K \).

An element \( \alpha \in L \) that is algebraic over \( K \) has a well-defined minimal polynomial \( m(t) \in K[t] \); this is the unique monic polynomial over \( K \) of smallest degree such that \( m(\alpha) = 0 \).

### 17.2 Simple Algebraic Extensions

As before, we can define the subfield of \( L \) generated by a subset \( X \subseteq L \) together with some subfield \( K \), and we employ the same notation \( K(X) \) for this field. We say that it is obtained by adjoining \( X \) to \( K \). The terms finitely generated extension and simple extension generalize without change.

We mimic the classification of simple extensions in \( \mathbb{C} \) of Chapter 5. Simple transcendental extensions are easy to analyse, and we obtain the same result: every simple transcendental extension of a field \( K \) is isomorphic to \( K(t) : K \), where \( K(t) \) is the field of rational expressions over \( K \). As before, it is trivial to prove that any simple transcendental extension \( K(\alpha) \) of \( K \) is isomorphic to \( K(t) : K \), the field of rational expressions in one indeterminate \( t \). Moreover, there is an isomorphism that carries \( t \) to \( \alpha \).

The algebraic case is slightly trickier; again, the key is irreducible polynomials. The result that opens up the whole area is:

**Theorem 17.2**

Let \( K \) be a field and suppose that \( m \in K[t] \) is irreducible and monic. Let \( I \) be the ideal of \( K[t] \) consisting of all multiples of \( m \). Then \( K[t]/I \) is a field, and there is a natural monomorphism \( \iota : K \rightarrow K[t]/I \) such that \( \iota(k) = I + k \).

**Proof** First, observe that \( I \) really is an ideal (Exercise 17.1). We know on general nonsense grounds that \( K[t]/I \) is a ring. So suppose that \( I + f \in K[t]/I \) is not the zero element, which in this case means that \( f \notin I \). Then \( f \) is not a multiple of \( m \),
and since \( m \) is irreducible, the hcf of \( f \) and \( m \) is 1. Therefore, there exist \( a, b \in K[t] \) such that \( af + bm = 1 \). We claim that the multiplicative inverse of \( I + f \) is \( I + a \). To prove this, compute:

\[
(I + f)(I + a) = I + fa = I + (1 - bm) = I + 1
\]

since \( bm \in I \) by definition. But \( I + 1 \) is the multiplicative identity of \( K[t]/I \). Therefore, \( K[t]/I \) is a field.

Define \( \iota : K \to K[t]/I \) by \( \iota(k) = I + k \). It is easy to check that \( \iota \) is a homomorphism. We show that it is one-to-one. Suppose that \( \iota(a) = \iota(b) \) for \( a, b \in K \). Therefore, \( \iota(a - b) = I + 0 \). If \( a \neq b \), then \( 1 = (a - b)(a - b)^{-1} \). Then \( \iota(1) = \iota(a - b)\iota((a - b)^{-1}) = I + 0 \). But \( \iota(1) = I + 1 \) and \( 1 \not\in I \), so \( \iota(1) \neq I + 0 \). This contradiction shows that \( a \neq b \), so \( \iota \) is a monomorphism. 

This proof can be made more elegant and more general (see Exercise 17.2). We can (and do) identify \( K \) with its image \( \iota(K) \), so now \( K \subseteq K[t]/I \). It is easy to see that the minimal polynomial of \( I + t \in K[t]/I \) over \( K \) is \( m(t) \). Indeed, \( m(I + t) = I + m(t) = I + 0 \). (This is the only place we use the fact that \( m \) is monic. But if \( m \) is irreducible and not monic, then some multiple \( km \), with \( k \in K \), is irreducible and monic; moreover, \( m \) and \( km \) determine the same ideal \( I \).) We can now prove a classification theorem for simple algebraic extensions.

**THEOREM 17.3**

Let \( K(\alpha) : K \) be a simple algebraic extension, where \( \alpha \) has minimal polynomial \( m \) over \( K \). Then \( K(\alpha) : K \) is isomorphic to \( K[t]/I : K \), where \( I \) is the ideal of \( K[t] \) consisting of all multiples of \( m \). Moreover, there is a natural isomorphism in which \( \alpha \mapsto \text{the coset } I + t \).

**PROOF** Define a map \( \phi : K[t] \to K(\alpha) \) by \( \phi(f(t)) = f(\alpha) \). This is clearly a ring homomorphism. Its image is the whole of \( K(\alpha) \), and its kernel consists of all multiples of \( m(t) \) by Lemma 5.6 (generalized). Now \( K(\alpha) = \text{im}(\phi) \cong K[t]/\ker(\phi) = K[t]/I \), as required.

We can now prove a preliminary version of the result that \( K \) and \( m \) between them determine the extension \( K(\alpha) \).

**THEOREM 17.4**

Suppose \( K(\alpha) : K \) and \( K(\beta) : K \) are simple algebraic extensions, such that \( \alpha \) and \( \beta \) have the same minimal polynomial \( m \) over \( K \). Then the two extensions are isomorphic, and the isomorphism of the large fields can be taken to map \( \alpha \) to \( \beta \).
PROOF  By Lemma 5.9 (generalized) every element \( x \in K(\alpha) \) is uniquely expressible in the form
\[
x = x_0 + x_1 \alpha + \cdots + x_n \alpha^n \quad (x_1, \ldots, x_n \in K)
\]
where \( n = \partial m - 1 \). Define a map \( \phi : K(\alpha) \to K(\beta) \) by
\[
\phi(x) = x_0 + x_1 \beta + \cdots + x_n \beta^n
\]
By Lemma 5.9 (generalized) \( \phi \) is onto and one-to-one. Obviously,
\[
\phi(x + y) = \phi(x) + \phi(y)
\]
We shall show that \( \phi(xy) = \phi(x)\phi(y) \), for any \( x, y \in K(\alpha) \). Let \( x = f(\alpha), y = g(\alpha), xy = h(\alpha) \), where \( f, g, h \) are polynomials over \( K \) of degree < \( \partial m \). Then
\[
f(\alpha)g(\alpha) - h(\alpha) = xy - xy = 0
\]
By Lemma 5.6 (generalized) \( m \) divides \( fg - h \), so there exists a polynomial \( q \) over \( K \) such that \( fg = mq + h \). Since \( \partial h < \partial m \), it follows that \( h \) is the remainder on dividing \( fg \) by \( m \). By the same reasoning, \( f(\beta)g(\beta) = h(\beta) \). Thus
\[
\phi(xy) = h(\beta) = f(\beta)g(\beta) = \phi(x)\phi(y)
\]
so \( \phi \) is an isomorphism. Since \( \phi \) is the identity on \( K \), the two extensions are isomorphic; clearly, \( \phi(\alpha) = \beta \).

17.3 Splitting Fields

In Chapter 9 we defined the term splitting field: a polynomial \( f \in K[t] \) splits in \( L \) if it can be expressed as a product of linear factors over \( L \). There, we appealed to the Fundamental Theorem of Algebra to construct the splitting field for a given complex polynomial. In the general case, the Fundamental Theorem of Algebra is not available to us. (There is a version of it (Exercise 17.3) but in order to prove that version, we must be able to construct splitting fields without appealing to that version of the Fundamental Theorem of Algebra.) And, there is no longer a unique splitting field — though splitting fields are unique up to isomorphism.

We start by generalizing Definitions 9.1 and 9.3.

**Definition 17.5**  If \( K \) is a field and \( f \) is a polynomial over \( K \), then \( f \) splits over \( K \) if it can be expressed as a product of linear factors
\[
f(t) = k(t - \alpha_1) \cdots (t - \alpha_n)
\]
where \( k, \alpha_1, \ldots, \alpha_n \in K \).
**Definition 17.6** Let $K$ be a field and let $\Sigma$ be an extension of $K$. Then $\Sigma$ is a splitting field for the polynomial $f$ over $K$ if

1. $f$ splits over $\Sigma$.

2. If $K \subseteq \Sigma' \subseteq \Sigma$ and $f$ splits over $\Sigma'$, then $\Sigma' = \Sigma$.

Our aim is to show that for any field $K$, any polynomial over $K$ has a splitting field $\Sigma$, and this splitting field is unique up to isomorphism of extensions.

The work that we have already done allows us to construct, in the abstract, any simple extension of a field $K$. Specifically, any simple transcendental extension $K(\alpha)$ of $K$ is isomorphic to the field $K(t)$ of rational expressions in $t$ over $K$. And if $m \in K[t]$ is irreducible and monic, and $I$ is the ideal of $K[t]$ consisting of all multiples of $m$, then $K[t]/I$ is a simple algebraic extension $K(\alpha)$ of $K$ where $\alpha = I + t$ has minimal polynomial $m$ over $K$. Moreover, all simple algebraic extensions of $K$ arise (up to isomorphism) by this construction.

**Definition 17.7** We refer to these constructions as adjoining $\alpha$ to $K$.

When we were working with subfields $K$ of $\mathbb{C}$, we could assume that the element(s) being adjoined were in $\mathbb{C}$, so all we had to do was take the field they generate, together with $K$. Now we do not have a big field in which to work, so we have to create the fields along with the elements that we need.

We construct a splitting field by adjoining to $K$ elements that are to be thought of as the zeros of $f$. We already know how to do this for irreducible polynomials, see Theorem 5.7 (generalized), so we split $f$ into irreducible factors and work on these separately.

**Theorem 17.8**

If $K$ is any field and $f$ is any polynomial over $K$, then there exists a splitting field for $f$ over $K$.

**Proof** Use induction on the degree $\partial f$. If $\partial f = 1$ there is nothing to prove, for $f$ splits over $K$: If $f$ does not split over $K$, then it has an irreducible factor $f_1$ of degree $\geq 1$. Using Theorem 5.7 (generalized) we adjoin $\sigma_1$ to $K$, where $f_1(\sigma_1) = 0$. Then in $K(\sigma_1)[t]$ we have $f = (t - \sigma_1)g$ where $\partial g = \partial f - 1$. By induction, there is a splitting field $\Sigma$ for $g$ over $K(\sigma_1)$. But then $\Sigma$ is clearly a splitting field for $f$ over $K$.

It would appear at first sight that we might construct different splitting fields for $f$ by varying the choice of irreducible factors. In fact, splitting fields (for given $f$ and $K$) are unique up to isomorphism. The statements and proofs are exactly as in Lemma 9.5 and Theorem 9.6, and we do not repeat them here.
17.4 Normality

Just as in our previous work, the properties that drive the Galois correspondence are normality and separability. We discuss normality in this section, and separability in the next.

Because we suppressed explicit use of over \( \mathbb{C} \) from our earlier definition, it remains seemingly unchanged:

**Definition 17.9** A field extension \( L : K \) is normal if every irreducible polynomial \( f \) over \( K \) that has at least one zero in \( L \) splits in \( L \).

So does the proof of the main result about normality and splitting fields.

**Theorem 17.10**

A field extension \( L : K \) is normal and finite if and only if \( L \) is a splitting field for some polynomial over \( K \).

**Proof** The same as Theorem 9.9, except that the splitting field becomes a splitting field.

17.5 Separability

We generalize Definition 9.10:

**Definition 17.11** An irreducible polynomial \( f \) over a field \( K \) is separable over \( K \) if it has no multiple zeros in a splitting field.

Since the splitting field is unique up to isomorphism, it is irrelevant which splitting field we use to check this property.

**Example 17.12**

Consider \( f(t) = t^2 + t + 1 \) over \( \mathbb{Z}_2 \). This time we cannot use \( \mathbb{C} \), so we must go back to the basic construction for a splitting field. The field \( \mathbb{Z}_2 \) has two elements, 0 and 1. We note that \( f \) is irreducible, so we may adjoin an element \( \zeta \) such that \( \zeta \) has minimal polynomial \( f \) over \( \mathbb{Z}_2 \). Then \( \zeta^2 + \zeta + 1 = 0 \) so that \( \zeta^2 = 1 + \zeta \) (remember, the characteristic is 2) and the elements 0, 1, \( \zeta \), 1 + \( \zeta \) form a field. This follows from Lemma 5.9 (generalized). It can also be verified directly by working out addition and
17.5 Separability

multiplication tables:

<td>1</td>
<td>$\zeta$</td>
</tr>
</tbody>
</table>

The sort of calculation needed in the second table runs like this:

$$\zeta(1 + \zeta) = \zeta + \zeta^2 = \zeta + \zeta + 1 = 1.$$ 

Therefore, $\mathbb{Z}_2(\zeta)$ is a field with four elements. Now $f$ splits over $\mathbb{Z}_2(\zeta)$:

$$t^2 + t + 1 = (t - \zeta)(t - 1 - \zeta)$$

but over no smaller field. Hence $\mathbb{Z}_2(\zeta)$ is a splitting field for $f$ over $\mathbb{Z}_2$.

**DEFINITION 17.13** An irreducible polynomial over a field $K$ is inseparable over $K$ if it is not separable over $K$.

**LEMMA 17.14**

Let $K$ be a field of characteristic $p > 0$. Then the map $\phi : K \rightarrow K$ defined by $\phi(k) = k^p$ ($k \in K$) is a field monomorphism. If $K$ is finite, then $\phi$ is an automorphism.

**PROOF** Let $x, y \in K$. Then

$$\phi(xy) = (xy)^p = x^p y^p = \phi(x)\phi(y)$$

Also,

$$\phi(x + y) = (x + y)^p = x^p + px^{p-1}y + \binom{p}{2}x^{p-2}y^2 + \cdots + px^{p-1}y + y^p$$

(17.1)
by the binomial theorem. We claim that the binomial coefficient
\[
\binom{p}{r}
\]
is divisible by \( p \) if \( 1 \leq r \leq p - 1 \). To prove this, observe that the binomial coefficient is an integer, and
\[
\binom{p}{r} = \frac{p!}{r!(p-r)!}
\]
The factor \( p \) in the numerator cannot cancel unless \( r = 0, p \).
Hence the sum in (17.1) reduces to its first and last terms, so
\[
\phi(x + y) = x^p + y^p = \phi(x) + \phi(y)
\]
Therefore, \( \phi \) is a homomorphism. We prove that \( \phi \) is one-to-one. If \( \phi(x) = \phi(y) \), then \( \phi(x-y) = 0 \). If \( x \neq y \), then \( \phi(1) = \phi((x-y)(x-y)^{-1}) = \phi(x-y)\phi((x-y)^{-1}) = 0 \).
But \( \phi(1) = 1 \neq 0 \), a contradiction. Therefore, \( \phi \) is a monomorphism.
If \( K \) is finite, then any monomorphism \( K \to K \) is automatically onto by counting elements, so \( \phi \) is an automorphism in this case.

**Definition 17.15** If \( K \) is a field of characteristic \( p > 0 \), then the map \( \phi : K \to K \) defined by \( \phi(k) = k^p \) \((k \in K)\) is the Frobenius monomorphism or Frobenius map of \( K \). When \( K \) is finite, \( \phi \) is called the Frobenius automorphism of \( K \).

If you try this on the field \( \mathbb{Z}_5 \), it turns out that \( \phi \) is the identity map, which is not very inspiring. The same goes for \( \mathbb{Z}_p \) for any prime \( p \). But for the field of Example 7.12 we have \( \phi(0) = 0, \phi(1) = 1, \phi(\zeta) = 1 + \zeta, \phi(1 + \zeta) = \zeta \), so that \( \phi \) is not always the identity.

**Example 17.16**
We use the Frobenius map to give an example of an inseparable polynomial. Let \( K_0 = \mathbb{Z}_p \) for prime \( p \). Let \( K = K_0(u) \) where \( u \) is transcendental over \( K_0 \), and let
\[
f(t) = t^p - u \in K[t]
\]
Let \( \Sigma \) be a splitting field for \( f \) over \( K \), and let \( \tau \) be a zero of \( f \) in \( \Sigma \). Then \( \tau^p = u \).
Now use the Frobenius map:
\[
(t - \tau)^p = t^p - \tau^p = t^p - u = f(t)
\]
Thus if \( \sigma^p - u = 0 \), then \( (\sigma - \tau)^p = 0 \) so that \( \sigma = \tau \); all the zeros of \( f \) in \( \Sigma \) are equal.
It remains to show that \( f \) is irreducible over \( K \). Suppose that \( f = gh \) where \( g, h \in K[t] \), and \( g \) and \( h \) have lower degree than \( f \). We must have \( g(t) = (t - \tau)^s \)
where $0 < s < p$ by uniqueness of factorization. Hence the constant coefficient $\tau^2$ of $g$ lies in $K$. This implies that $\tau \in K$, for there exist integers $a$ and $b$ such that $as + bp = 1$, and since $\tau^{as+bp} \in K$ it follows that $\tau \in K$. Then $\tau = v(u)/w(u)$ where $v, w \in K_0[u]$, so

$$v(u)^p - u(w(u))^p = 0$$

But the terms of highest degree cannot cancel. Hence $f$ is irreducible.

The formal derivative $Df$ of a polynomial $f$ can be defined for any underlying field $K$.

**Definition 17.17** Suppose that $K$ is a field, and let

$$f(t) = a_0 + a_1 t + \cdots + a_n t^n \in K[t]$$

Then the formal derivative of $f$ is the polynomial

$$Df = a_1 + 2a_2 t + \cdots + na_n t^{n-1}$$

Note that here the elements $2, \ldots, n$ belong to $K$, not $\mathbb{Z}$. In fact they are what we briefly wrote as $2^*, \ldots, n^*$.

Lemma 9.13 states that a polynomial $f \neq 0$ has a multiple zero in a splitting field if and only if $f$ and $Df$ have a common factor of degree $\geq 1$. This lemma remains valid over any field, and has the same proof. Using the formal derivative, we can characterize inseparable irreducible polynomials:

**Proposition 17.18**

If $K$ is a field of characteristic 0, then every irreducible polynomial over $K$ is separable over $K$.

If $K$ has characteristic $p > 0$, then an irreducible polynomial $f$ over $K$ is inseparable if and only if

$$f(t) = k_0 + k_1 t^p + \cdots + k_r t^{p^r}$$

where $k_0, \ldots, k_r \in K$.

**Proof** By Lemma 9.13 (generalized), an irreducible polynomial $f$ over $K$ is inseparable if and only if $f$ and $Df$ have a common factor of degree $\geq 1$. If so, then since $f$ is irreducible and $Df$ has smaller degree than $f$, we must have $Df = 0$. Thus if

$$f(t) = a_0 + \cdots + a_n t^n$$

then $na_n = 0$ for all integers $n > 0$. For characteristic 0 this is equivalent to $a_n = 0$ for all $n$. For characteristic $p > 0$ it is equivalent to $a_n = 0$ if $p$ does not divide $n$. Let $k_i = a_{ip}$, and the result follows.

[]
The condition on $f$ for inseparability over fields of characteristic $p$ can be expressed by saying that only powers of $t$ that are multiples of $p$ occur. That is, $f(t) = g(t^p)$ for some polynomial $g$ over $K$.

We now define three more uses of the word separable.

**Definition 17.19** An arbitrary polynomial over a field $K$ is separable over $K$ if all its irreducible factors are separable over $K$.

If $L : K$ is an extension, then an algebraic element $\alpha \in L$ is separable over $K$ if its minimal polynomial over $K$ is separable over $K$.

An algebraic extension $L : K$ is a separable extension if every $\alpha \in L$ is separable over $K$.

For algebraic extensions, separability carries over to intermediate fields.

**Lemma 17.20**

Let $L : K$ be a separable algebraic extension and let $M$ be an intermediate field.

Then $M : K$ and $L : M$ are separable.

**Proof** Clearly, $M : K$ is separable. Let $\alpha \in L$, and let $m_K$ and $m_M$ be its minimal polynomials over $K$, $M$, respectively. Now $m_M|m_K$ in $M[t]$. But $\alpha$ is separable over $K$ so $m_K$ is separable over $K$, hence $m_M$ is separable over $M$. Therefore, $L : M$ is a separable extension.

We end this section by proving that an extension generated by the zeros of a separable polynomial is separable. To prove this, we first prove:

**Lemma 17.21**

Let $L : K$ be an extension of fields of characteristic $p$, and let $\alpha \in L$ be algebraic over $K$. Then $\alpha$ is separable over $K$ if and only if $K(\alpha^p) = K(\alpha)$.

**Proof** Since $\alpha$ is a zero of $t^p - \alpha^p \in K(\alpha^p)[t]$, which equals $(t - \alpha)^p$ by the Frobenius map, the minimal polynomial of $\alpha$ over $K(\alpha^p)$ must divide $(t - \alpha)^p$ and hence be $(t - \alpha)^s$ for some $s \leq p$.

If $\alpha$ is separable over $K$, then it is separable over $K(\alpha^p)$. Therefore, $(t - \alpha)^s$ has simple zeros, so $s = 1$. Therefore, $\alpha \in K(\alpha^p)$, so $K(\alpha^p) = K(\alpha)$.

For the converse, suppose that $\alpha$ is inseparable over $K$. Then its minimal polynomial over $K$ has the form $g(t^p)$ for some $g \in K[t]$. Thus $\alpha$ has degree $p\deg g$ over $K$. In contrast, $\alpha^p$ is a zero of $g$, which has smaller degree $\deg g$. Thus $K(\alpha^p)$ and $K(\alpha)$ have different degrees over $K$, so cannot be equal.

**Theorem 17.22**

If $L : K$ is a field extension such that $L$ is generated over $K$ by a set of separable algebraic elements, then $L : K$ is separable.
17.6 Galois Theory for Abstract Fields

PROOF We may assume that $K$ has characteristic $p$. It is sufficient to prove that the set of elements of $L$ that are separable over $K$ is closed under addition, subtraction, multiplication, and division. (Indeed, subtraction and division are enough.) We give the proof for addition; the other cases are similar.

Suppose that $\alpha, \beta \in L$ are separable over $K$. Observe that

$$K(\alpha + \beta, \beta) = K(\alpha, \beta) = K(\alpha^p, \beta^p) = K(\alpha^p + \beta^p, \beta^p)$$

(17.2)

using Lemma 17.21 for the middle equality. Now consider the towers

$$K \subseteq K(\alpha + \beta) \subseteq K(\alpha + \beta, \beta)$$

$$K \subseteq K(\alpha^p + \beta^p) \subseteq K(\alpha^p + \beta^p, \beta^p)$$

and consider the corresponding degrees. Using the Frobenius map it is easy to see that

$$[K(\alpha^p + \beta^p, \beta^p) : K(\alpha^p + \beta^p)] \leq [K(\alpha + \beta, \beta) : K(\alpha + \beta)]$$

and

$$[K(\alpha^p + \beta^p) : K] \leq [K(\alpha + \beta) : K]$$

However,

$$[K(\alpha^p + \beta^p, \beta^p) : K] = [K(\alpha + \beta, \beta) : K]$$

by (17.2). Now the tower law implies that the above inequalities of degrees must actually be equalities. The result follows. □

17.6 Galois Theory for Abstract Fields

Finally, we can set up the Galois correspondence as in Chapter 12. Everything works provided that we work with a normal separable field extension rather than just a normal one. As we remarked in that context, separability is automatic for subfields of $\mathbb{C}$. So there should be no difficulty in reworking the theory in the more general context.

Note in particular that Theorem 11.14 (generalized) requires separability for fields of prime characteristic.

Because of its importance, we restate the Fundamental Theorem of Galois Theory:

**Theorem 17.23 (Fundamental Theorem, General Case)**

If $L : K$ is a finite separable normal field extension, with Galois group $G$, and if $\mathcal{F}, G, *, \dagger$ are defined as before, then:
1. The Galois group $G$ has order $[L : K]$.

2. The maps $*$ and $\dagger$ are mutual inverses, and set up an order-reversing one-to-one correspondence between $\mathcal{F}$ and $\mathcal{G}$.

3. If $M$ is an intermediate field, then

$$[L : M] = |M^*| \quad [M : K] = |G|/|M^*|$$

4. An intermediate field $M$ is a normal extension of $K$ if and only if $M^*$ is a normal subgroup of $G$.

5. If an intermediate field $M$ is a normal extension of $K$, then the Galois group of $M : K$ is isomorphic to the quotient group $G/M^*$.

**Proof** Mimic the proof of Theorem 12.1 and look out for steps that require separability.

Another thing to look out for is the uniqueness of the splitting field of a polynomial; now it is unique only up to isomorphism. For example, we defined the Galois group of a polynomial $f$ over $K$ to be the Galois group of $\Sigma : K$, where $\Sigma$ is the splitting field of $f$. When $K$ is a subfield of $\mathbb{C}$, the subfield $\Sigma$ is unique. In general, it is unique up to isomorphism, so the Galois group of $f$ is unique up to isomorphism. That suits us fine.

What about radical extensions? In characteristic $p$, inseparability raises its ugly head, and its effect is serious. For example, $t^p - 1 = (t - 1)^p$ by the Frobenius map, so the only $p$th root of unity is 1. The definition of "radical extension" has to be changed in characteristic $p$, and we shall not go into the details. However, everything carries through unchanged to fields with characteristic 0.

We have now reworked the entire theory established in previous chapters, generalizing from subfields of $\mathbb{C}$ to arbitrary fields. Now we can pick up the thread again, but from now on, the abstract formalism is there if we need it.

---

**Exercises**

17.1 Let $K$ be a field, and let $f(t) \in K[t]$. Prove that the set of all multiples of $f$ is an ideal of $K[t]$.

17.2 Let $\phi : K \to R$ be a ring homomorphism, where $K$ is a field and $R$ is a ring. Prove that $\phi$ is one-to-one. (Note that in this book rings have identity elements 1 and homomorphisms preserve such elements.)

17.3* Prove by transfinite induction that every field can be embedded in an algebraically closed field, its algebraic closure. (Hint: Keep adjoining zeros of irreducible polynomials until there are none left.)
17.4* Prove that algebraic closures are unique up to isomorphism. More strongly, if $K$ is any field, and $A$, $B$ are algebraic closures of $K$, show that the extensions $A : K$ and $B : K$ are isomorphic.

17.5 Let $\mathbb{A}$ denote the set of all complex numbers that are algebraic over $\mathbb{Q}$. The elements of $\mathbb{A}$ are called algebraic numbers. Show that $\mathbb{A}$ is a field, as follows.

a. Prove that a complex number $\alpha \in \mathbb{A}$ if and only if $[\mathbb{Q}(\alpha) : \mathbb{Q}] < \infty$.

b. Let $\alpha$, $\beta \in \mathbb{A}$. Use the Tower Law to show that $[\mathbb{Q}(\alpha, \beta) : \mathbb{Q}] < \infty$.

c. Use the Tower Law to show that $[\mathbb{Q}(\alpha + \beta) : \mathbb{Q}] < \infty$, $[\mathbb{Q}(-\alpha) : \mathbb{Q}] < \infty$, $[\mathbb{Q}(\alpha\beta) : \mathbb{Q}] < \infty$, and if $\alpha \neq 0$, then $[\mathbb{Q}(\alpha^{-1}) : \mathbb{Q}] < \infty$.

d. Therefore, $\mathbb{A}$ is a field.

17.6 Prove that $\mathbb{R}[t]/(t^2 + 1)$ is isomorphic to $\mathbb{C}$.

17.7 Of the extensions defined in Exercise 4.3, which are simple algebraic? Which are simple transcendental?

17.8 Find the minimal polynomials over the small field of the following elements in the following extensions:

a. $\alpha$ in $K : P$ where $K$ is the field of Exercise 16.6 and $P$ is its prime subfield.

b. $\alpha$ in $\mathbb{Z}_3(t)(\alpha) : \mathbb{Z}_3(t)$ where $t$ is indeterminate and $\alpha^2 = t + 1$.

17.9 For which of the following values of $m(t)$ do there exist extensions $K(\alpha)$ of $K$ for which $\alpha$ has minimal polynomial $m(t)$?

a. $m(t) = t^2 + 1$, $K = \mathbb{Z}_3$

b. $m(t) = t^2 + 1$, $K = \mathbb{Z}_5$

c. $m(t) = t^7 - 3t^6 + 4t^3 - t - 1$, $K = \mathbb{R}$

17.10 Show that for fields of characteristic 2 there exist quadratic equations that cannot be solved by adjoining square roots of elements in the field. (*Hint: Try $\mathbb{Z}_2$.)

17.11 Show that we can solve quadratic equations over a field of characteristic 2 if, as well as square roots, we adjoin elements $\sqrt{\overline{k}}$ defined to be solutions of the equation

$$(\sqrt{\overline{k}})^2 + \sqrt{\overline{k}} = k.$$ 

17.12 Show that the two zeros of $t^2 + t - k = 0$ in the previous question are $\sqrt{\overline{k}}$ and $1 + \sqrt{\overline{k}}$.

17.13 Let $K = \mathbb{Z}_3$. Find all irreducible quadratics over $K$, and construct all possible extensions of $K$ by an element with quadratic minimal polynomial. Into how
many isomorphism classes do these extensions fall? How many elements do they have?

17.14 Mark the following true or false.

a. Every minimal polynomial is irreducible.

b. Every irreducible polynomial over a field $K$ can be the minimal polynomial of some element $\alpha$ in a simple algebraic extension of $K$.

c. A transcendental element does not have a minimal polynomial.

d. Any field has infinitely many non-isomorphic simple transcendental extensions.

e. Splitting fields for a given polynomial are unique.

f. Splitting fields for a given polynomial are unique up to isomorphism.

g. The polynomial $r^6 - r^3 + 1$ is separable over $\mathbb{Z}_3$. 
Chapter 18

The General Polynomial

As we saw in Chapter 8, the so-called general polynomial is in fact very special. It is a polynomial whose coefficients do not satisfy any algebraic relations. This property makes it in some respects simpler to work with than, say, a polynomial over $\mathbb{Q}$, and in particular it is easier to calculate its Galois group. As a result, we can show that the general quintic polynomial is not soluble by radicals without assuming as much group theory as we did in Chapter 15, and without having to prove the Theorem on Natural Irrationalities, Theorem 8.14.

Chapter 15 makes it clear that the Galois group of the general polynomial of degree $n$ should be the whole symmetric group $S_n$, and we will show that this contention is correct. This immediately leads to the insolubility of the general quintic. Moreover, our knowledge of the structure of $S_2, S_3, S_4$ can be used to find a unified method to solve the general quadratic, cubic, and quartic equations. Further work, not described here, leads to a method for solving any quintic that is soluble by radicals, and finding out whether this is the case (see Berndt, Spearman, and Williams, 2002).

18.1 Transcendence Degrees

Until now we have not had to deal much with transcendental extensions; indeed, the assumption of finiteness of the extensions has been central to the theory. We now need to consider a wider class of extensions, which still have a flavour of finiteness.

**DEFINITION 18.1** An extension $L : K$ is finitely generated if $L = K(\alpha_1, \ldots, \alpha_n)$ where $n$ is finite.

Here the $\alpha_j$ may be either algebraic or transcendental over $K$.

**DEFINITION 18.2** If $t_1, \ldots, t_n$ are transcendental elements over a field $K$, all lying inside some extension $L$ of $K$, then they are independent if there is no nontrivial polynomial $p$ over $K$ (in $n$ indeterminates) such that $p(t_1, \ldots, t_n) = 0$ in $L$.

Thus, for example, if $t$ is transcendental over $K$ and $u$ is transcendental over $K(t)$, then $K(t, u)$ is a finitely generated extension of $K$, and $t, u$ are independent. On the
other hand, \( t \) and \( u = t^2 + 1 \) are both transcendental over \( K \), but are connected by the polynomial equation \( t^2 + 1 - u = 0 \), so are not independent.

The next result describes the structure of a finitely generated extension.

**LEMMA 18.3**

*If \( L : K \) is finitely generated, then there exists an intermediate field \( M \) such that*

1. \( M = K(\alpha_1, \ldots, \alpha_r) \) where the \( \alpha_i \) are independent transcendental elements over \( K \).

2. \( L : M \) is a finite extension.

**PROOF** We know that \( L = K(\beta_1, \ldots, \beta_n) \). If all the \( \beta_j \) are algebraic over \( K \), then \( L : K \) is finite by Lemma 6.11 (generalized) and we may take \( M = K \). Otherwise, some \( \beta_j \) is transcendental over \( K \). Call this \( \alpha_1 \). If \( L : K(\alpha_1) \) is not finite, there exists some \( \beta_k \) transcendental over \( K(\alpha_1) \). Call this \( \alpha_2 \). We may continue this process until \( M = K(\alpha_1, \ldots, \alpha_r) \) is such that \( L : M \) is finite. By construction, the \( \alpha_j \) are independent transcendental elements over \( K \).

A result due to Ernst Steinitz says that the integer \( r \) that gives the number of independent transcendental elements does not depend on the choice of \( M \).

**LEMMA 18.4 (Steinitz Exchange Lemma)**

*With the notation of Lemma 18.3, if there is another intermediate field \( N = K(\beta_1, \ldots, \beta_s) \) such that \( \beta_1, \ldots, \beta_s \) are independent transcendental elements over \( K \) and \( L : N \) is finite, then \( r = s \).*

**PROOF** Since \( [L : M] \) is finite, \( \beta \) is algebraic over \( M \). Therefore, there is a polynomial equation

\[ p(\beta_1, \alpha_1, \ldots, \alpha_r) = 0 \]

Some \( \alpha_j \), without loss of generality \( \alpha_1 \), actually occurs in this equation. Then \( \alpha_1 \) is algebraic over \( K(\beta_1, \alpha_2, \ldots, \alpha_r) \) and \( L : K(\beta_1, \alpha_2, \ldots, \alpha_r) \) is finite. Inductively we can replace successive \( \alpha_j \) by \( \beta_j \), so that

\[ L : K(\beta_1, \ldots, \beta_r) \]

is finite. If \( s > r \), then \( \beta_{r+1} \) must be algebraic over \( K(\beta_1, \ldots, \beta_r) \), a contradiction. Therefore, \( s \leq r \). Similarly, \( r \leq s \). The lemma is proved.

**DEFINITION 18.5** The integer \( r \) defined in Lemma 18.3 is the transcendence degree of \( L : K \). By Lemma 4, the value of \( r \) is well defined.
For example, consider \( K(t, \alpha, u) : K \), where \( t \) is transcendental over \( K, \alpha^2 = t \), and 
\( u \) is transcendental over \( K(t, \alpha) \). Then \( M = K(t, u) \) where \( t \) and \( u \) are independent transcendental elements over \( K \), and

\[
K(t, \alpha, u) : M = M(\alpha) : M
\]
is finite. The transcendence degree is 2.

It is straightforward to show that an extension \( K(\alpha_1, \ldots, \alpha_r) : K \) by independent transcendental elements \( \alpha_i \) is isomorphic to \( K(t_1, \ldots, t_r) : K \) where \( K(t_1, \ldots, t_r) \) is the field of rational expressions in the indeterminates \( t_i \). Thus we have:

**Proposition 18.6**

A finitely generated extension \( L : K \) has transcendence degree \( r \) if and only if there is an intermediate field \( M \) such that \( L \) is a finite extension of \( M \) and \( M : K \) is isomorphic to \( K(t_1, \ldots, t_r) : K \).

## 18.2 Elementary Symmetric Polynomials

Usually we are given a polynomial and wish to find its zeros. But it is also possible to work in the opposite direction; given the zeros and their multiplicities, reconstruct the polynomial. This is a far easier problem which has a complete general solution, as we saw in Section 8.7 for complex polynomials. We recap the main ideas.

Consider a polynomial of degree \( n \) having its full quota of \( n \) zeros (counting multiplicities). It is, therefore, a product of \( n \) linear factors

\[
f(t) = k(t - \alpha_1) \ldots (t - \alpha_n)
\]

where \( k \in K \) and the \( \alpha_j \) are the zeros in \( K \) (not necessarily distinct). Suppose that

\[
f(t) = a_0 + a_1 t + \cdots + a_n t^n
\]

If we expand the first product and equate coefficients with the second expression, we get the expected result:

\[
a_n = k
a_{n-1} = -k(\alpha_1 + \cdots + \alpha_n)
\]

\[
a_{n-2} = k(\alpha_1 \alpha_2 + \alpha_1 \alpha_3 + \cdots + \alpha_{n-1} \alpha_n)
\]

\[
\ldots
\]

\[
a_0 = k(-1)^n \alpha_1 \alpha_2 \ldots \alpha_n
\]

The expression in \( \alpha_1, \ldots, \alpha_n \) on the right (neglecting factors \( \pm k \)) is the elementary symmetric polynomials of Chapter 8, but now interpreted as elements of \( K(t_1, \ldots, t_n) \).
where \( K \) can be any field. Moreover, the elementary symmetric polynomials here are evaluated as \( t_j = \alpha_j \), for \( 1 \leq j \leq n \), a minor technical distinction but one worth remarking.

The elementary symmetric polynomials are symmetric in the sense that they are unchanged by permuting the indeterminates \( t_j \). This property suggests:

**Definition 18.7** A polynomial \( q \in K(t_1, \ldots, t_n) \) is symmetric if

\[
q(t_{\sigma(1)}, \ldots, t_{\sigma(n)}) = q(t_1, \ldots, t_n)
\]

for all permutations \( \sigma \in S_n \).

There are other symmetric polynomials apart from the elementary ones, for example, \( t_1^2 + \cdots + t_n^2 \), but they can all be expressed in terms of elementary symmetric polynomials:

**Theorem 18.8** Over a field \( K \), any symmetric polynomial in \( t_1, \ldots, t_n \) can be expressed as a polynomial of smaller or equal degree in the elementary symmetric polynomials \( s_r(t_1, \ldots, t_n) \) \( (r = 0, \ldots, n) \).

**Proof** See Exercise 8.2 (generalized to any field).

A slightly weaker version of this result is proved in Corollary 18.10. We need Theorem 18.8 to prove that \( \pi \) is transcendental (Chapter 24). The quickest proof of Theorem 18.8 is by induction, and full details can be found in any of the older algebra texts (Salmon, 1885, p. 57, van der Waerden, 1953, p. 81).

---

### 18.3 The General Polynomial

Let \( K \) be any field, and let \( t_1, \ldots, t_n \) be independent transcendental elements over \( K \). The symmetric group \( S_n \) can be made to act as a group of \( K \)-automorphisms of \( K(t_1, \ldots, t_n) \) by defining

\[
\sigma(t_i) = t_{\sigma(i)}
\]

for all \( \sigma \in S_n \), and extending any rational expressions \( \phi \) by defining

\[
\sigma(\phi(t_1, \ldots, t_n)) = \phi(t_{\sigma(1)}, \ldots, t_{\sigma(n)})
\]

It is easy to prove that \( \sigma \), extended in this way, is a \( K \)-automorphism.

For example, if \( n = 4 \) and \( \sigma \) is the permutation

\[
\begin{pmatrix}
1 & 2 & 3 & 4 \\
2 & 4 & 3 & 1
\end{pmatrix}
\]
then \( \sigma(t_1) = t_2, \ \sigma(t_2) = t_4, \ \sigma(t_3) = t_3, \) and \( \sigma(t_4) = t_1. \) Moreover, as a typical case,

\[
\sigma\left( \frac{t_1^5 t_4}{t_2^4 - 7t_3} \right) = \frac{t_2^5 t_1}{t_4^4 - 7t_3}
\]

Clearly, distinct elements of \( S_n \) give rise to distinct \( K \)-automorphisms.

The fixed field \( F \) of \( S_n \) obviously contains all the symmetric polynomials in the \( t_i \) and, in particular, the elementary symmetric polynomials \( s_r = s_r(t_1, \ldots, t_n). \) We show that these generate \( F. \)

**Lemma 18.9**

*With the above notation, \( F = K(s_1, \ldots, s_n). \)*

**Proof** First we show that

\[
[K(t_1, \ldots, t_n): K(s_1, \ldots, s_n)] \leq n!
\]

by induction on \( n. \) Consider the double extension

\[
K(t_1, \ldots, t_n) \supseteq K(s_1, \ldots, s_n, t_n) \supseteq K(s_1, \ldots, s_n)
\]

Now \( f(t_n) = 0, \) where

\[
f(t) = t^n - s_1 t^{n-1} + \cdots + (-1)^n s_n
\]

so that

\[
[K(s_1, \ldots, s_n, t_n): K(s_1, \ldots, s_n)] \leq n
\]

If we let \( s'_1, \ldots, s'_{n-1} \) be the elementary symmetric polynomials in \( t_1, \ldots, t_{n-1}, \) and define \( s'_0 = 1, \) then

\[
s_j = t_n s'_{j-1} + s'_j
\]

and, therefore,

\[
K(s_1, \ldots, s_n, t_n) = K(t_n, s'_1, \ldots, s'_{n-1})
\]

By induction

\[
[K(t_1, \ldots, t_n): K(s, \ldots, s_n, t_n)]
\]

\[
= [K(t_n(t_1, \ldots, t_{n-1}): K(t_n)(s'_1, \ldots, s'_{n-1})] \leq (n - 1)!
\]

so by the Tower Law (generalized) the induction step goes through. \( \square \)
The General Polynomial

Now \( K(s_1, \ldots, s_n) \) is clearly contained in the fixed field \( F \) of \( \mathbb{S}_n \). By Theorem 10.5 (generalized)

\[
[K(t_1, \ldots, t_n) : F] = |\mathbb{S}_n| = n!
\]

so by the above \( F = K(s_1, \ldots, s_n) \).

**COROLLARY 18.10**

Every symmetric polynomial in \( t_1, \ldots, t_n \) over \( K \) can be written as a rational expression in \( s_1, \ldots, s_n \).

**PROOF** Symmetric polynomials lie inside the fixed field \( F \).

Compare this result with Theorem 18.8.

**LEMMA 18.11**

With the above notation, \( s_1, \ldots, s_n \) are independent transcendental elements over \( K \).

**PROOF** Here \( K(t_1, \ldots, t_n) \) is a finite extension of \( K(s_1, \ldots, s_n) \) and hence they both have the same transcendence degree over \( K \), namely, \( n \). Therefore, the \( s_j \) are independent, for otherwise the transcendence degree of \( K(s_1, \ldots, s_n) : K \) would be smaller than \( n \).

**DEFINITION 18.12** Let \( K \) be a field and let \( s_1, \ldots, s_n \) be independent transcendental elements over \( K \). The general polynomial of degree \( n \) "over" \( K \) is the polynomial

\[
t^n - s_1 t^{n-1} - s_2 t^{n-2} - \cdots - (-1)^n s_n
\]

over the field \( K(s_1, \ldots, s_n) \).

The quotation marks are used because the polynomial is really over the field \( K(s_1, \ldots, s_n) \), not \( K \).

**THEOREM 18.13**

For any field \( K \) let \( g \) be the general polynomial of degree \( n \) "over" \( K \), and let \( \Sigma \) be a splitting field for \( g \) over \( K(s_1, \ldots, s_n) \). Then the zeros \( t_1, \ldots, t_n \) of \( g \) in \( \Sigma \) are independent transcendental elements over \( K \), and the Galois group of \( \Sigma : K \) is the symmetric group \( \mathbb{S}_n \).

**PROOF** The extension \( \Sigma : K(s_1, \ldots, s_n) \) is finite by Theorem 9.9, so the transcendence degree of \( \Sigma : K \) is equal to that of \( K(s_1, \ldots, s_n) : K \), namely, \( n \). Since \( \Sigma = K(t_1, \ldots, t_n) \), the \( t_j \) are independent transcendental elements over \( K \), since any
algebraic relation between them would lower the transcendence degree. The $s_j$ are now the elementary symmetric polynomials in $t_1, \ldots, t_n$ by Theorem 18.8. As above, $S_n$ acts as a group of automorphisms of $\Sigma = K(t_1, \ldots, t_n)$, and by Lemma 18.9 the fixed field is $K(s_1, \ldots, s_n)$. By Theorem 11.14, $\Sigma : K(s_1, \ldots, s_n)$ is separable and normal (normality also follows from the definition of $\Sigma$ as a splitting field), and by Theorem 10.5 its degree is $|S_n| = n!$. Then by Theorem 17.23(1) the Galois group has order $n!$, and contains $S_n$, so it equals $S_n$. □

From Theorem 15.9 and Corollary 14.8 we deduce:

**Theorem 18.14**

If $K$ is a field of characteristic zero and $n \geq 5$, then the general polynomial of degree $n$ "over" $K$ is not soluble by radicals.

---

### 18.4 Cyclic Extensions

Because this polynomial "over" $K$ is actually a polynomial over the extension field $K(s_1, \ldots, s_n)$, with $n$ independent transcendental elements $s_j$, Theorem 18.14 does not imply that any particular polynomial over $K$ of degree $n \geq 5$ is not soluble by radicals. For example, the theorem does not rule out the possibility that every quintic might be soluble by radicals, but that the formula involved varies so much from case to case that no general formula holds. However, when the general polynomial of degree $n$ "over" $K$ can be solved by radicals, it is easy to deduce a solution by radicals of any polynomial of degree $n$ over $K$, by substituting elements of $K$ for $s_1, \ldots, s_n$ in the solution. This is the source of the generality of the general polynomial. From Theorem 18.14, the best that we can hope for using radicals is a solution of polynomials of degree $\leq 4$. We fulfill this hope by analysing the structure of $S_n$ for $n \leq 4$, and appealing to a converse to Theorem 15.9. This converse is proved by showing that cyclic extensions — extensions with cyclic Galois group — are closely linked to radicals.

**Definition 18.15** Let $L : K$ be a finite normal extension with Galois group $G$. The norm of an element $a \in L$ is

$$N(a) = \tau_1(a)\tau_2(a) \ldots \tau_n(a)$$

where $\tau_1, \ldots, \tau_n$ are the elements of $G$.

Clearly, $N(a)$ lies in the fixed field of $G$ (use Lemma 10.4) so if the extension is also separable, then $N(a) \in K$.

The next result is traditionally referred to as Hilbert's Theorem 90 from its appearance in his 1893 report on algebraic numbers.
THEOREM 18.16 (Hilbert's Theorem 90)
Let \( L : K \) be a finite normal extension with cyclic Galois group \( G \) generated by an element \( \tau \). Then \( a \in L \) has norm \( N(a) = 1 \) if and only if

\[
a = b / \tau(b)
\]

for some \( b \in L \), where \( b \neq 0 \).

**PROOF** Let \( |G| = n \). If \( a = b / \tau(b) \) and \( b \neq 0 \), then

\[
N(a) = a \tau(a) \tau^2(a) \cdots \tau^{n-1}(a)
\]

\[
= \frac{b \tau(b) \tau^2(b) \cdots \tau^{n-1}(b)}{\tau(b) \tau^2(b) \cdots \tau^n(b)}
\]

\[
= 1
\]

since \( \tau^n = 1 \).

Conversely, suppose that \( N(a) = 1 \). Let \( c \in L \), and define

\[
d_0 = ac
\]

\[
d_1 = (a \tau(a)) \tau(c)
\]

\[
\ldots
\]

\[
d_j = [a \tau(a) \cdots \tau^j(a)] \tau^j(c)
\]

for \( 0 \leq j \leq n - 1 \). Then

\[
d_{n-1} = N(a) \tau^{n-1}(c) = \tau^{n-1}(c)
\]

Further,

\[
d_{j+1} = a \tau(d_j) \quad (0 \leq j \leq n - 2)
\]

Define

\[
b = d_0 + d_1 + \cdots + d_{n-1}
\]

We choose \( c \) to make \( b \neq 0 \). Suppose on the contrary that \( b = 0 \) for all choices of \( c \).

Then for any \( c \in L \)

\[
\lambda_0 \tau^0(c) + \lambda_1 \tau(c) + \cdots + \lambda_{n-1} \tau^{n-1}(c) = 0
\]

where

\[
\lambda_j = a \tau(a) \cdots \tau^j(a)
\]

belongs to \( L \). Hence the distinct automorphisms \( \tau^j \) are linearly dependent over \( L \), contrary to Lemma 10.1.
Therefore, we can choose $c$ so that $b \neq 0$. But now
\[
\tau(b) = \tau(d_0) + \cdots + \tau(d_{n-1}) = (1/a)(d_1 + \cdots + d_{n-1}) + \tau^a(c) = (1/a)(d_0 + \cdots + d_{n-1}) = b/a
\]
Thus $a = b/\tau(b)$ as claimed.

**THEOREM 18.17**
Suppose that $L : K$ is a finite separable normal extension whose Galois group $G$ is cyclic of prime order $p$, generated by $\tau$. Assume that the characteristic of $K$ is 0 or is prime to $p$, and that $t^p - 1$ splits in $K$. Then $L = K(\alpha)$, where $\alpha$ is a zero of an irreducible polynomial $t^p - a$ over $K$ for some $a \in K$.

**PROOF** The $p$ zeros of $t^p - 1$ from a group of order $p$, which must, therefore, be cyclic since any group of prime order is cyclic. Because a cyclic group consists of powers of a single element, the zeros of $t^p - 1$ are the powers of some $\varepsilon \in K$ where $\varepsilon^p = 1$. But then
\[
N(\varepsilon) = \varepsilon \cdots \varepsilon = 1
\]
since $\varepsilon \in K$ so that $\tau^i(\varepsilon) = \varepsilon$ for all $i$. By Theorem 18.16, $\varepsilon = \alpha/\tau(\alpha)$ for some $\alpha \in L$. Therefore,
\[
\tau(\alpha) = \varepsilon^{-1}\alpha \quad \tau^2(\alpha) = \varepsilon^{-2}\alpha \quad \cdots \quad \tau^i(\alpha) = \varepsilon^{-i}\alpha
\]
and $a = \alpha^p$ is fixed by $G$, so lies in $K$. Now $K(\alpha)$ is a splitting field for $t^p - a$ over $K$. The $K$-automorphisms $1, \tau, \ldots, \tau^{p-1}$ map $\alpha$ to distinct elements, so they give $p$ distinct $K$-automorphisms of $K(\alpha)$. By Theorem 17.23(1) the degree $[K(\alpha) : K] \geq p$. But $[L : K] = |G| = p$, so $L = K(\alpha)$. Hence $t^p - a$ is the minimal polynomial of $\alpha$ over $K$, otherwise we would have $[K(\alpha) : K] < p$. Being a minimal polynomial, $t^p - a$ is irreducible over $K$.

We can now prove the promised converse to Theorem 15.9. Compare with Lemma 8.16(2).

**THEOREM 18.18**
Let $K$ be a field of characteristic 0 and let $L : K$ be a finite normal extension with soluble Galois group $G$. Then there exists an extension $R$ of $L$ such that $R : K$ is radical.

**PROOF** All extensions are separable since the characteristic is 0. We use induction on $|G|$. The result is clear when $|G| = 1$. If $|G| \neq 1$ we take a maximal proper normal
subgroup $H$ of $G$, which exists since $G$ is a finite group. Then $G/H$ is simple, since $H$ is maximal, and is also soluble by Theorem 14.4(2). By Theorem 14.6, $G/H$ is cyclic of prime order $p$. Let $N$ be a splitting field over $L$ of $t^p - 1$. Then $N : K$ is normal, for by Theorem 9.9 $L$ is a splitting field over $K$ of some polynomial $f$, so $N$ is a splitting field over $L$ of $(t^p - 1)f$, which implies that $N : K$ is normal by Theorem 9.9.

The Galois group of $N : L$ is abelian by Lemma 15.6, and by Theorem 17.23(5) $\Gamma(L : K)$ is isomorphic to $\Gamma(N : K)/\Gamma(N : L)$. By Theorem 14.4(3) (generalized), $\Gamma(N : K)$ is soluble. Let $M$ be the subfield of $N$ generated by $K$ and the zeros of $t^p - 1$. Then $N : M$ is normal. Now $M : K$ is clearly radical, and since $L \subseteq N$ the desired result will follow provided we can find an extension $R$ of $N$ such that $R : M$ is radical.

We claim that the Galois group of $N : M$ is isomorphic to a subgroup of $G$. Let us map any $M$-automorphism $\tau$ of $N$ into its restriction $\tau|_L$. Since $L : K$ is normal, $\tau|_L$ is a $K$-automorphism of $L$, and there is a group homomorphism

$$\phi : \Gamma(N : M) \to \Gamma(L : K)$$

If $\tau \in \ker(\phi)$, then $\tau$ fixes all elements of $M$ and $L$, which generate $N$. Therefore, $\tau = 1$, so $\phi$ is a monomorphism, which implies that $\Gamma(N : M)$ is isomorphic to a subgroup $J$ of $\Gamma(L : K)$.

If $J = \phi(\Gamma(N : M))$ is a proper subgroup of $G$, then by induction there is an extension $R$ of $N$ such that $R : M$ is radical.

The remaining possibility is that $J = G$. Then we can find a subgroup $I \triangleleft \Gamma(N : M)$ of index $p$, namely, $I = \psi^{-1}(H)$. Let $P$ be the fixed field $I^\psi$. Then $[P : M] = p$ by Theorem 17.23(3), $P : M$ is normal by Theorem 17.23(4), and $t^p - 1$ splits in $M$. By Theorem 18.17 (generalized), $P = M(\alpha)$ where $\alpha^p = a \in M$. But $N : P$ is a normal extension with soluble Galois group of order smaller than $|G|$, so by induction there exists an extension $R$ of $N$ such that $R : P$ is radical. But then $R : M$ is radical, and the theorem is proved.

To deal with field of characteristic $p > 0$ we must define radical extensions differently. As well as adjoining elements $\alpha$ such that $\alpha^p$ lies in the given field we must also allow adjunction of elements $\alpha$ such that $\alpha^p - \alpha$ lies in the given field (where $p$ is the same as the characteristic). It is then true that a polynomial is soluble by radicals if and only if its Galois group is soluble. The proof differs in considering extensions of degree $p$ over fields of characteristic $p$, when Theorem 18.17 (generalized) breaks down, and extensions of the second type above come in. If we do not modify the definition of solubility by radicals, then although every soluble polynomial has soluble group, the converse need not hold — indeed, some quadratic polynomials, having abelian Galois group, will not be soluble by radicals (see Exercises 18.12 and 18.13).

Since a splitting field is always a normal extension, we have:
THEOREM 18.19
Over a field of characteristic zero, a polynomial is soluble by radicals if and only if it has a soluble Galois group.

PROOF Use Theorems 15.9 and 18.18.

18.5 Solving Quartic Equations

The general polynomial of degree $n$ has Galois group $S_n$, and we know that for $n \leq 4$ this is soluble (Chapter 14). Theorem 18.19, therefore, implies that for a field $K$ of characteristic zero, the general polynomial of degree $\leq 4$ can be solved by radicals. We already know this from the classical tricks in Chapter 1, but now we can use the structure of the symmetric group to explain, in a unified way, why those tricks work.

18.5.1 Linear Equations

$$t - s_1$$

Trivially, $t_1 = s_1$ is a zero.

The Galois group here is trivial, and adds little to the discussion except to confirm that the zero must lie in $K$.

18.5.2 Quadratic Equations

$$t^2 - s_1 t + s_2$$

Let the zeros be $t_1$ and $t_2$. The Galois group $S_2$ consists of the identity and a map interchanging $t_1$ and $t_2$. Hence

$$(t_1 - t_2)^2$$

is fixed by $S_2$, so lies in $K(s_1, s_2)$. By explicit calculation

$$(t_1 - t_2)^2 = s_1^2 - 4s_2$$

Hence

$$t_1 - t_2 = \pm \sqrt{s_1^2 - 4s_2}$$

$$t_1 + t_2 = s_1$$
and we have the familiar formula
\[ t_1, t_2 = \frac{s_1 \pm \sqrt{s_1^2 - 4s_2}}{2} \]

18.5.3 Cubic Equations

\[ t^3 - s_1t^2 + s_2t - s_3 \]

Let the zeros be \( t_1, t_2, t_3 \). The Galois group \( S_3 \) has a series

\[ 1 \triangleleft A_3 \triangleleft S_3 \]

with abelian quotients. Adjoin an element \( \omega \neq 1 \) such that \( \omega^3 = 1 \). Consider

\[ y = t_1 + \omega t_2 + \omega^2 t_3 \]

The elements of \( A_3 \) permute \( t_1, t_2, t_3 \) cyclically and, therefore, multiply \( y \) by a power of \( \omega \). Hence \( y^3 \) is fixed by \( A_3 \). Similarly, if

\[ z = t_1 + \omega^2 t_2 + \omega t_3 \]

then \( z^3 \) is fixed by \( A_3 \). Now any odd permutation in \( S_3 \) interchanges \( y^3 \) and \( z^3 \), so that \( y^3 + z^3 \) and \( y^3 z^3 \) are fixed by the whole of \( S_3 \), hence lie in \( K(s_1, s_2, s_3) \). (Explicit formulas are given in the final section of this chapter.) Hence \( y^3 \) and \( z^3 \) are zeros of a quadratic over \( K(s_1, s_2, s_3) \) that can be solved as in part (b). Taking cube roots we know \( y \) and \( z \). But since

\[ s_1 = t_1 + t_2 + t_3 \]

it follows that

\[ t_1 = \frac{1}{3}(s_1 + y + z) \]
\[ t_2 = \frac{1}{3}(s_1 + \omega y + \omega z) \]
\[ t_3 = \frac{1}{3}(s_1 + \omega^2 y + \omega^2 z) \]

18.5.4 Quartic Equations

\[ t^4 - s_1t^3 + s_2t^2 - s_3t + s_4 \]

Let the zeros be \( t_1, t_2, t_3, t_4 \). The Galois group \( S_4 \) has a series

\[ 1 \triangleleft V \triangleleft A_4 \triangleleft S_4 \]
18.5 Solving Quartic Equations

with abelian quotients, where

\[ V = \{1, (12)(34), (13)(24), (14)(23)\} \]

is the Klein four-group. It is, therefore, natural to consider the three expressions

\[
\begin{align*}
y_1 &= (t_1 + t_2)(t_3 + t_4) \\
y_2 &= (t_1 + t_3)(t_2 + t_4) \\
y_3 &= (t_1 + t_4)(t_2 + t_3)
\end{align*}
\]

These are permuted among themselves by any permutation in \( S_4 \), so that all the elementary symmetric polynomials in \( y_1, y_2, y_3 \) lie in \( K(s_1, s_2, s_3, s_4) \). (Explicit formulas are indicated below.) Then \( y_1, y_2, y_3 \) are the zeros of a certain cubic polynomial over

\[ K(s_1, s_2, s_3, s_4) \]

called the resolvent cubic. Since

\[ t_1 + t_2 + t_3 + t_4 = s_1 \]

we can find three quadratic polynomials whose zeros are \( t_1 + t_2 \) and \( t_3 + t_4, t_1 + t_3 \) and \( t_2 + t_4, t_1 + t_4 \) and \( t_2 + t_3 \). From these it is easy to find \( t_1, t_2, t_3, t_4 \).

18.5.5 Explicit Formulas

For completeness, we now state the explicit formulas whose existence is alluded to above. For details of the calculations, see van der Waerden (1953, pp. 177–182). Compare with Section 1.4.

Cubic. By the Tschirnhaus transformation

\[ u = t - \frac{1}{3}s_1 \]

the general cubic polynomial takes the form

\[ u^3 + pu + q \]

If we can find the zeros of this it is an easy matter to find them for the general cubic. The above procedure for this polynomial leads to

\[
\begin{align*}
y^3 + z^3 &= -27q \\
y^3z^3 &= -27p^3
\end{align*}
\]

implying that \( y^3 \) and \( z^3 \) are the zeros of the quadratic polynomial

\[ t^2 + 27qt - 27p^3 \]

This yields Cardano’s formula (1.7).

Quartic. The relevant Tschirnhaus transformation is now

\[ u = t - \frac{1}{4}s_1 \]
which reduces the quartic to the form

\[ t^4 + pt^2 + qt + r \]

In the above procedure, we therefore have

\[
\begin{align*}
\gamma_1 + \gamma_2 + \gamma_3 &= 2p \\
\gamma_1 \gamma_2 + \gamma_1 \gamma_3 + \gamma_2 \gamma_3 &= p^2 - 4r \\
\gamma_1 \gamma_2 \gamma_3 &= -q^2
\end{align*}
\]

The resolvent cubic takes the form

\[ t^3 - 2pt^2 + (p^2 - 4r)t + q^2 \]

Figure 18.1: Cardano, the first person to publish solutions of cubic and quartic equations.
(which is a thinly disguised form of (1.11) with \( t = -2u \)). Its zeros are \( y_1, y_2, y_3 \), and

\[
    t_1 = \frac{1}{2} (\sqrt{-y_1} + \sqrt{-y_2} + \sqrt{-y_3}) \\
    t_2 = \frac{1}{2} (\sqrt{-y_1} - \sqrt{-y_2} - \sqrt{-y_3}) \\
    t_3 = \frac{1}{2} (-\sqrt{-y_1} + \sqrt{-y_2} - \sqrt{-y_3}) \\
    t_4 = \frac{1}{2} (-\sqrt{-y_1} - \sqrt{-y_2} + \sqrt{-y_3})
\]

the square roots being chosen so that

\[\sqrt{-y_1}\sqrt{-y_2}\sqrt{-y_3} = -q\]

---

**Exercises**

18.1 If \( K \) is a countable field and \( L : K \) is finitely generated, show that \( L \) is countable. Hence show that \( \mathbb{R} : \mathbb{Q} \) and \( \mathbb{C} : \mathbb{Q} \) are not finitely generated.

18.2 Calculate the transcendence degrees of the following extensions:

   a. \( \mathbb{Q}(t, u, v, w) : \mathbb{Q} \) where \( t, u, v, w \) are independent transcendental elements over \( \mathbb{Q} \)

   b. \( \mathbb{Q}(t, u, v, w) : \mathbb{Q} \) where \( t^2 = 2, u \) is transcendental over \( \mathbb{Q}(t), v^3 = t + 5 \), and \( w \) is transcendental over \( \mathbb{Q}(t, u, v) \)

   c. \( \mathbb{Q}(t, u, v) : \mathbb{Q} \) where \( t^2 = u^3 = v^4 = 7 \)

18.3 Show that in Lemma 18.3 the degree \([L : M]\) is not independent of the choice of \( M \). (Hint: Consider \( K(t^2) \) as a subfield of \( K(t) \).)

18.4 Suppose that \( K \subseteq L \subseteq M \), and each of \( M : K \), \( L : K \) is finitely generated. Show that \( M : K \) and \( L : K \) have the same transcendence degree if and only if \( M : L \) is finite.

18.5* For any field \( K \) show that \( t^3 - 3t + 1 \) is either irreducible or splits in \( K \). (Hint: Show that any zero is a rational expression in any other zero.)

18.6 Let \( K \) be a field of characteristic zero, and suppose that \( L : K \) is finite and normal with Galois group \( G \). For any \( a \in L \) define the *trace*

\[ T(a) = \tau_1(a) + \cdots + \tau_n(a) \]
where \( \tau_1, \ldots, \tau_n \) are the distinct elements of \( G \). Show that \( T(a) \in K \) and that \( T \) is a surjective map \( L \to K \).

18.7 If in the previous exercise \( G \) is cyclic with generator \( \tau \), show that \( T(a) = 0 \) if and only if \( a = b - \tau(b) \) for some \( b \in L \).

18.8 Solve by radicals the following polynomial equations over \( \mathbb{Q} \):
   a. \( t^3 - 7t + 5 = 0 \)
   b. \( t^3 - 7t + 6 = 0 \)
   c. \( t^4 + 5t^3 - 2t - 1 = 0 \)
   d. \( t^4 + 4t + 2 = 0 \)

18.9 Show that a finitely generated algebraic extension is finite, and hence find an algebraic extension that is not finitely generated.

8.10* Let \( \theta \) have minimal polynomial
   \[ t^3 + at^2 + bt + c \]
   over \( \mathbb{Q} \). Find necessary and sufficient conditions in terms of \( a, b, c \) such that \( \theta = \phi^2 \) where \( \phi \in \mathbb{Q}(\theta) \). (Hint: Consider the minimal polynomial of \( \phi \).) Hence or otherwise express \( \sqrt[3]{28} - 3 \) as a square in \( \mathbb{Q}(\sqrt[3]{28}) \), and \( \sqrt[5]{5} - \sqrt[4]{4} \) as a square in \( \mathbb{Q}(\sqrt[5]{5}, \sqrt[4]{4}) \) (see Ramamujan, 1962, p. 329).

8.11* Let \( \Gamma \) be a finite group of automorphisms of \( K \) with fixed field \( K_0 \). Let \( t \) be transcendental over \( K \). For each \( \sigma \in \Gamma \) show there is a unique automorphism \( \sigma' \) of \( K(t) \) such that
   \[ \sigma'(k) = \sigma(k) \quad (k \in K) \]
   \[ \sigma'(t) = t \]
   
   Show that the \( \sigma' \) form a group \( \Gamma' \) isomorphic to \( \Gamma \), with fixed field \( K_0(t) \).

18.12 Let \( K \) be a field of characteristic \( p \). Suppose that \( f(t) = t^p - t - \alpha \in K[t] \). If \( \beta \) is a zero of \( f \), show that the zeros of \( f \) are \( \beta + k \) where \( k = 0, 1, \ldots, p - 1 \). Deduce that either \( f \) is irreducible over \( K \) or \( f \) splits in \( K \).

8.13* If \( f \) in Exercise 18.12 is irreducible over \( K \), show that the Galois group of \( f \) is cyclic. State and prove a characterization of finite extensions with soluble Galois group — radical extensions — in characteristic \( p \).

18.14 Mark the following true or false.
   a. Every finite extension is finitely generated.
   b. Every finitely generated extension is algebraic.
   c. The transcendence degree of a finitely generated extension is invariant under isomorphism.
d. If $t_1, \ldots, t_n$ are independent transcendental elements, then their elementary symmetric polynomials are also independent transcendental elements.

e. The Galois group of the general polynomial of degree $n$ is soluble for all $n$.

f. The general quintic polynomial is soluble by radicals.

g. The only proper subgroups of $S_3$ are 1 and $A_3$.

h. The transcendence degree of $\mathbb{Q}(t): \mathbb{Q}$ is 1.

i. The transcendence degree of $\mathbb{Q}(t^2): \mathbb{Q}$ is 2.
Chapter 19

Regular Polygons

We return with more sophisticated weapons to the time-honoured problem of ruler-and-compass construction. We shall consider the following question: for which values of \( n \) can the regular \( n \)-sided polygon be constructed by ruler and compasses?

The ancient Greeks knew of constructions for 3-, 5-, and 15-gons; they also knew how to construct a \( 2n \)-gon given an \( n \)-gon, by the obvious method of bisecting the angles. We describe these constructions in Section 19.1. For about 2000 years little progress was made beyond the Greeks. If you answered Example 7.13, then you will have got further than they did. It seemed obvious that the Greeks had found all the constructible regular polygons . . . Then, on 30 March 1796, Gauss made the remarkable discovery that the regular 17-gon can be constructed (Figure 19.1). He was 19 years old at the time. So pleased was he with this discovery that he resolved to dedicate the rest of his life to mathematics, having until then been unable to decide between that and the study of languages. In his *Disquisitiones Arithmeticae*, reprinted as Gauss (1966), he stated necessary and sufficient conditions for constructibility of the regular \( n \)-gon, and proved their sufficiency; he claimed to have a proof of necessity although he never published it. Doubtless he did; Gauss knew a proof when he saw one.

19.1 What Euclid Knew

Euclid's *Elements* gets down to business straight away. The first regular polygon constructed there is the equilateral triangle, in Book 1 Proposition 1. Figure 19.2 makes the construction fairly clear.

The square also makes its appearance in Book 1:

**PROPOSITION 19.1 (Euclid)**

On a given straight line to describe a square.

In the proof, which we give in detail to illustrate Euclid's style, notation such as [1,31] refers to Proposition 31 of Book 1 of the Elements. The proof is taken from Heath (1956), the classic edition of Euclid's Elements. Refer to Figure 19.3 for the lettering.
Figure 19.1: The first entry in Gauss's notebook records his construction of the regular 17-gon.

Figure 19.2: Euclid's construction of an equilateral triangle.
19.1 What Euclid Knew

![Diagram of a square]

**Figure 19.3:** Euclid's construction of a square.

**PROOF** Let AB be the given straight line; thus it is required to describe a square on the straight line AB.

Let AC be drawn at right angles to the straight line AB from the point A on it [1, 11], and let AD be made equal to AB; through the point D let DE be drawn parallel to AB, and through the point B let BE be drawn parallel to AD [1,31].

Therefore, ADEB is a parallelogram; therefore, AB is equal to DE, and AD to BE [1, 34]. But AB is equal to AD; therefore, the four straight lines BA, AD, DE, EB are equal to one another; therefore, the parallelogram ADEB is equilateral.

I say next that it is also right-angled. For, since the straight line AD falls upon the parallels AB, DE, the angles BAD, ADE are equal to two right angles [1, 29].

But the angle BAD is also right; therefore, the angle ADE is also right.

And in parallelogrammic areas the opposite sides and angles are equal to one another [1, 34]; therefore, each of the opposite angles ABE, BED is also right. Therefore, ADEB is right-angled. And it was also proved equilateral. Therefore, it is a square; and it is described on the straight line AB. Q.E.F.

Here Q.E.F. (*quod erat faciendum* — that which was to be done) replaces the familiar Q.E.D. (*quod erat demonstrandum* — that which was to be proved) because this is not a theorem but a construction. In any case, the Latin arises in later translations; Euclid wrote in Greek. Now imagine you are a Victorian schoolboy — it always was a schoolboy in those days — trying to learn Euclid’s proof by heart, including the exact choice of letters in the diagrams.

The construction of the regular pentagon has to wait until Book 4 Proposition 11, because it depends on some quite sophisticated ideas, notably Proposition 10 of Book 4: *To construct an isosceles triangle having each of the angles at the base double of the remaining one.* In modern terms, construct a triangle with angles $4\pi/5$, $4\pi/5$, $2\pi/5$. Euclid’s method for doing this is shown in Figure 19.4. Given AB, find C so that $AB \times BC = CA^2$. To do that, see Book 2 Proposition 11, which is itself quite complicated — the construction here is essentially the famous “golden section,” a name that seems to have been introduced in 1835 by Martin Ohm (Herz-Fischler, 1998; Livio, 2002). Euclid’s method is given in Exercise 19.10. Next, draw the circle centre...
Regular Polygons

Figure 19.4: Euclid's construction of an isosceles triangle with base angles $4\pi/5$.

Figure 19.5: Euclid's construction of a regular pentagon. Make ACD similar to triangle ABD in Figure 19.4, and proceed from there.

A radius AB, and find D such that BD = AC. Then triangle ABD is the one required. With this triangle shape under his belt, Euclid then constructs the regular pentagon. Figure 19.5 makes his method clear.

19.2 Which Constructions are Possible?

That, however, was not the end of the story. In order to obtain necessary and sufficient conditions for the existence of a ruler-and-compass construction, we must prove a more detailed theorem than Theorem 4. This requires a careful examination of which constructions are possible.
LEMMA 19.2
If $P$ is a subset of $\mathbb{R}^2$ containing the points $(0, 0)$ and $(1, 0)$, then the point $(x, y)$ can be constructed from $P$ whenever $x$ and $y$ lie in the subfield of $\mathbb{R}$ generated by the coordinates of points in $P$.

PROOF Given any point $(x_0, y_0)$ it is obvious how to construct $(0, x_0)$ and $(0, y_0)$. From $(0, 0)$ and $(1, 0)$ we can construct the coordinate axes, and then proceed as in Figure 19.6.

If we are given $(0, x_0)$ and $(0, y_0)$, then the same construction in reverse gives $(x_0, y_0)$. Thus to prove the lemma it is sufficient to show that given $(0, x)$ and $(0, y)$ we can construct $(0, x + y), (0, x - y), (0, xy)$, and $(0, x/y)$ when $y \neq 0$. The first two are obvious. If we swing arcs of radius $y$ centre $(0, x)$, they cut the $y$-axis at $(0, x + y)$ and $(0, x - y)$. For the other two points we proceed as follows. Join $(1, 0)$ to $(0, y)$ and draw a line parallel to this through $(0, x)$ (see Exercise 19.1). This line cuts the $x$-axis at $(u, 0)$. By similar triangles $u/x = 1/y$, so that $u = x/y$. Taking $x = 1$ (the point $(0,1)$ is clearly constructible) we can construct $(1/y, 0)$, hence $(0, 1/y)$; by taking $1/y$ instead of $y$, we get $(xy, 0)$. From these we can find $(0, xy)$ and $(0, x/y)$. See Figure 19.7.

![Figure 19.6: Constructing $(0, x_0)$ and $(0, y_0)$ from $(x_0, y_0)$.

![Figure 19.7: Constructing $u = x/y$.](image-url)
LEMMA 19.3
Suppose that $K(\alpha) : K$ is an extension of degree 2 such that $K(\alpha) \subseteq \mathbb{R}$. Then any point $(z, w)$ of $\mathbb{R}^2$ whose coordinates $z, w$ lie in $K(\alpha)$ can be constructed from some suitable finite set of points whose coordinates lie in $K$.

PROOF  We have $\alpha^2 + p \alpha + q = 0$, where $p, q \in K$. Hence

$$\alpha = \frac{-p \pm \sqrt{p^2 - 4q}}{2}$$

and since $K(\alpha) \subseteq \mathbb{R}$ then $p^2 - 4q$ must be positive. Using Lemma 2 the result will follow if we can construct $(0, \sqrt{k})$ for any positive $k \in K$ from finitely many points $(x_r, y_r)$ where $x_r, y_r \in K$. To do this, construct $(-1, 0)$ and $(k, 0)$. Draw the semicircle with these points as the ends of a diameter, meeting the $y$-axis at $(0, v)$. By the intersecting chords theorem, $v^2 = 1 \cdot k$ so that $v = \sqrt{k}$ (see Figure 19.8).

THEOREM 19.4
Suppose that $K$ is a subfield of $\mathbb{R}$ generated by the coordinates of points in a subset $P \subseteq \mathbb{R}^2$. Let $\alpha, \beta$ lie in an extension $L$ of $K$, contained in $\mathbb{R}$, such that there exists a finite series of subfields

$$K = K_0 \subseteq K_1 \subseteq \cdots \subseteq K_r = L$$

such that $[K_{j+1} : K_j] = 2$ for $j = 0, \ldots, r-1$. Then the point $(\alpha, \beta)$ is constructible from $P$.

PROOF  Use induction on $r$. The case $r = 0$ is covered by Lemma 19.2. Otherwise, $(\alpha, \beta)$ is constructible from finitely many points whose coordinates lie in $K_{r-1}$ by Lemma 19.3. By induction, these points are constructible from $P$, so $(\alpha, \beta)$ is constructible from $P$.

From the proof of Theorem 19.4, the existence of such fields $K_i$ is also a necessary condition for $(\alpha, \beta)$ to be constructible from $P$. 
There is a more useful, but weaker, version of Theorem 19.4. To prove it, we first need:

**Lemma 19.5**

*If G is a finite group and \(|G| = 2^r\), then Z(G) contains an element of order 2.*

**Proof** Use the class equation (14.2). We have

\[ 1 + C_2 + \cdots + C_k = 2^r \]

so some \(C_j\) is odd. By Corollary 14.12 this \(C_j\) also divides \(2^r\), so we must have \(|C_j| = 1\). Hence \(Z(G) \neq 1\). Now apply Lemma 14.14.

**Corollary 19.6**

*If G is a finite group and \(|G| = 2^r\), then there exists a series of normal subgroups

\[ 1 = G_0 \subseteq \cdots \subseteq G_r = G \]

such that \(|G_j| = 2^j\) for \(0 \leq j \leq r\).*

**Proof** Use Lemma 19.5 and induction.

Now we can state and prove the promised modification of Theorem 19.4.

**Proposition 19.7**

*If \(K\) is a subfield of \(\mathbb{R}\), generated by the coordinates of points in a subset \(P \subseteq \mathbb{R}^2\), and if \(\alpha\) and \(\beta\) lie in a normal extension \(L\) of \(K\) such that \(L \subseteq \mathbb{R}\) and \([L : K] = 2^r\) for some integer \(r\), then \((\alpha, \beta)\) is constructible from \(P\).*

**Proof** \(L : K\) is separable since the characteristic is zero. Let \(G\) be the Galois group of \(L : K\). By Theorem 12.1(1) \(|G| = 2^r\), so \(G\) is a 2-group. By Corollary 19.6, \(G\) has a series of normal subgroups

\[ 1 = G_0 \subseteq G_1 \subseteq \cdots \subseteq G_r = G \]

such that \(|G_j| = 2^j\). Let \(K_j\) be the fixed field \(G_j^{1}_{r-j}\). Then by Theorem 12.1(3) \([K_{j+1} : K_j] = 2\) for all \(j\). By Theorem 19.4, \((\alpha, \beta)\) is constructible from \(P\).

---

**19.3 Regular Polygons**

We shall use a mixture of algebraic and geometric ideas to find those values of \(n\) for which the regular \(n\)-gon is constructible. To save breath, let us make the following (nonstandard):
DEFINITION 19.8  The positive integer \( n \) is constructive if the regular \( n \)-gon is constructible by ruler and compasses.

The first step is to reduce the problem to prime-power values of \( n \).

LEMMA 19.9

If \( n \) is constructive and \( m \) divides \( n \), then \( m \) is constructive. If \( m \) and \( n \) are coprime and constructive, then \( mn \) is constructive.

PROOF  If \( m \) divides \( n \), then we can construct a regular \( m \)-gon by joining every \( d \)th vertex of a regular \( n \)-gon, where \( d = n/m \).

If \( m \) and \( n \) are coprime, then there exist integers \( a, b \) such that \( am + bn = 1 \). Therefore,

\[
\frac{1}{mn} = \frac{1}{n} + \frac{1}{m}
\]

Hence from angles \( 2\pi/m \) and \( 2\pi/n \) we can construct \( 2\pi/mn \), and from this we obtain a regular \( mn \)-gon.

COROLLARY 19.10

Suppose that \( n = p_1^{a_1} \cdots p_r^{a_r} \) where \( p_1, \ldots, p_r \) are distinct primes. Then \( n \) is constructive if and only if each \( p_j^{a_j} \) is constructive.

Another obvious result:

LEMMA 19.11

For any positive integer \( \alpha \), the number \( 2^\alpha \) is constructive.

PROOF  The angle can be bisected by ruler and compasses, and the result follows by induction on \( \alpha \).

This reduces the problem of constructing regular polygons to the case when the number of sides is an odd prime power. Now we bring in the algebra. In the complex plane, the set of \( n \)th roots of unity forms the vertices of a regular \( n \)-gon. Further, these roots of unity are the zeros in \( \mathbb{C} \) of the polynomial

\[
t^n - 1 = (t - 1)(t^{n-1} + t^{n-2} + \cdots + t + 1)
\]

We concentrate on the second factor on the right-hand side.

LEMMA 19.12

Let \( p \) be a prime such that \( p^n \) is constructive. Let \( \zeta \) be a primitive \( p^n \)th root of unity in \( \mathbb{C} \). Then the degree of the minimal polynomial of \( \zeta \) over \( \mathbb{Q} \) is a power of 2.
19.3 Regular Polygons

**Proof** Take \( \zeta = \exp(2\pi i / p^n) \). Since \( p^n \) is constructive we can construct the point \((\alpha, \beta)\) where \( \alpha = \cos(2\pi / p^n) \) and \( \beta = \sin(2\pi / p^n) \) by projecting a vertex of the regular \( p^n \)-gon on to the coordinate axes. Hence by Theorem 19.4

\[
[\mathbb{Q}(\alpha, \beta) : \mathbb{Q}] = 2^r
\]

for some integer \( r \). Therefore,

\[
[\mathbb{Q}(\alpha, \beta, i) : \mathbb{Q}] = 2^{r+1}
\]

But \( \mathbb{Q}(\alpha, \beta, i) \) contains \( \alpha + i\beta = \zeta \), so that \( [\mathbb{Q}(\zeta) : \mathbb{Q}] \) is a power of 2, since \( \mathbb{Q}(\zeta) \subseteq \mathbb{Q}(\alpha, \beta, i) \). Hence the degree of the minimal polynomial of \( \zeta \) over \( \mathbb{Q} \) is a power of 2.

The next step is to calculate the relevant minimal polynomials to find their degrees. It turns out to be sufficient to consider \( p \) and \( p^2 \) only. The analysis explains the result we obtained in (3.3) by direct computation.

**Lemma 19.13**

If \( p \) is a prime and \( \zeta \) is a primitive \( p \)th root of unity in \( \mathbb{C} \), then the minimal polynomial of \( \zeta \) over \( \mathbb{Q} \) is

\[
f(t) = 1 + t + \cdots + t^{p-1}
\]

**Proof** Note that \( f(t) = (t^p - 1)/(t - 1) \). We know that \( f(\zeta) = 0 \) since \( \zeta^p - 1 = 0 \) and \( \zeta \neq 1 \). We are home if we can show that \( f(t) \) is irreducible. Put \( t = 1 + u \) where \( u \) is a new indeterminate. Then \( f(t) \) is irreducible over \( \mathbb{Q} \) if and only if \( f(1 + u) \) is irreducible. But

\[
f(1 + u) = \frac{(1 + u)^p - 1}{u} = u^{p-1} + ph(u)
\]

where \( h \) is a polynomial in \( u \) over \( \mathbb{Z} \) with constant term 1, by the usual remark about binomial coefficients. By Eisenstein’s Criterion, \( f(1 + u) \) is irreducible over \( \mathbb{Q} \).

**Lemma 19.14**

If \( p \) is a prime and \( \zeta \) is a primitive \( p^2 \)th root of unity in \( \mathbb{C} \), then the minimal polynomial of \( \zeta \) over \( \mathbb{Q} \) is

\[
g(t) = 1 + t^p + \cdots + t^{p(p-1)}
\]

**Proof** Note that \( g(t) = (t^{p^2} - 1)/(t^p - 1) \). Now \( \zeta^{p^2} - 1 = 0 \) but \( \zeta^p - 1 \neq 0 \) so \( g(\zeta) = 0 \). It suffices to show that \( g(t) \) is irreducible over \( \mathbb{Q} \). As before, we make the substitution \( t = 1 + u \). Then

\[
g(1 + u) = \frac{(1 + u)^{p^2} - 1}{(1 + u)^p - 1}
\]
and modulo \( p \) this is
\[
\frac{(1 + u^p)^2 - 1}{(1 + u^p) - 1} = u^{p(p-1)}
\]

Therefore, \( g(1 + u) = u^{p(p-1)} + pk(u) \) where \( k \) is a polynomial in \( u \) over \( \mathbb{Z} \). From the alternative expression
\[
g(1 + u) = 1 + (1 + u)^p + \cdots + (1 + u)^{p(p-1)}
\]
it follows that \( k \) has constant term 1. By Eisenstein’s Criterion, \( g(1 + u) \) is irreducible over \( \mathbb{Q} \).

We now come to the main result.

\[\Box\]

**THEOREM 19.15 (Gauss)**

The regular \( n \)-gon is constructible by ruler and compasses if and only if
\[
n = 2^r p_1 \cdots p_s
\]
where \( r \) and \( s \) are integers \( \geq 0 \), and \( p_1, \ldots, p_s \) are odd primes of the form
\[
p_j = 2^{2^j} + 1
\]
for positive integers \( r_j \).

**PROOF** Let \( n \) be constructive. Then \( n = 2^r p_1^{\alpha_1} \cdots p_s^{\alpha_s} \) where \( p_1, \ldots, p_s \) are distinct odd primes. By Corollary 19.10, each \( p_j^{\alpha_j} \) is constructive. If \( \alpha_j \geq 2 \), then \( p_j^{\alpha_j} \) is constructive by Theorem 19.4. Hence the degree of the minimal polynomial of a primitive \( p_j^{\alpha_j} \)th root of unity over \( \mathbb{Q} \) is a power of 2 by Lemma 19.12. By Lemma 19.14, \( p_j(p_j - 1) \) is a power of 2, which cannot happen since \( p_j \) is odd. Therefore \( \alpha_j = 1 \) for all \( j \). Therefore, \( p_j \) is constructive. By Lemma 19.13
\[
p_j = 1 - 2^{s_j}
\]
for suitable \( s_j \). Suppose that \( s_j \) has an odd divisor \( a > 1 \), so that \( s_j = ab \). Then
\[
p_j = (2^b)^a + 1
\]
which is divisible by \( 2^b + 1 \) since
\[
t^a + 1 = (t + 1)(t^{a-1} - t^{a-2} + \cdots + 1)
\]
when \( a \) is odd. So \( p_j \) cannot be prime. Hence \( s_j \) has no odd factors, so
\[
s_j = 2^{r_j}
\]
for some \( r_j > 0 \).
19.4 Fermat Numbers

This establishes the necessity of the given form of $n$. Now we prove sufficiency. By Corollary 19.10 we need consider only prime-power factors of $n$. By Lemma 19.11, $2^r$ is constructive. We must show that each $p_j$ is constructive. Let $\zeta$ be a primitive $p_j$th root of unity. Then

$$[\mathbb{Q}(\zeta) : \mathbb{Q}] = p_j - 1 = 2^a$$

for some $a$ by Lemma 19.13. Now $\mathbb{Q}(\zeta)$ is a splitting field for $f(t) = 1 + \cdots + t^{p-1}$ over $\mathbb{Q}$, so that $\mathbb{Q}(\zeta) : \mathbb{Q}$ is normal. It is also separable since the characteristic is zero. By Lemma 15.6, the Galois group $\Gamma(\mathbb{Q}(\zeta) : \mathbb{Q})$ is abelian. Let $K = \mathbb{R} \cap \mathbb{Q}(\zeta)$. Then

$$\cos(2\pi/p_j) = (\zeta + \zeta^{-1})/2 \in K$$

Now $\mathbb{Q}(\zeta) : K$ has degree 2, so by Theorem 12.1 $\Gamma(\mathbb{Q}(\zeta) : K)$ is a subgroup of $G = \Gamma(\mathbb{Q}(\zeta) : \mathbb{Q})$ of order 2. Further, it is a normal subgroup, since $G$ is abelian. Therefore, $K : \mathbb{Q}$ is a normal extension of degree $2^{a-1}$. By Proposition 19.7, the point $(\cos(2\pi/p_j), 0)$ is constructible. Hence $p_j$ is constructive, and the proof is complete.

---

19.4 Fermat Numbers

The problem now reduces to number theory. In 1640 Pierre de Fermat wondered when $2^k + 1$ is prime, and proved that a necessary condition is for $k$ to be a power of 2. Thus we are led to:

**Definition 19.16** The $n$th Fermat number is $F_n = 2^{2^n} + 1$.

The question becomes: when is $F_n$ prime?

Fermat noticed that $F_0 = 3$, $F_1 = 5$, $F_2 = 17$, $F_3 = 257$, and $F_4 = 65537$ are all prime. He conjectured that $F_n$ is prime for all $n$, but this was disproved by Euler in 1732, who proved that $F_5$ is divisible by 641 (Exercise 19.5). Knowledge of factors of Fermat numbers is changing almost daily, thanks to the prevalence of fast computers and special algorithms for primality testing of Fermat numbers (see Internet References). At the time of writing, the largest known composite Fermat number was $F_{382449}$, with a factor $3.2^{382447} + 1$, and 210 Fermat numbers were known to be composite.

The only known Fermat primes are still those found by Fermat himself:

**Proposition 19.17**

If $p$ is a prime, then the regular $p$-gon is constructible for $p = 2, 3, 5, 17, 257, 65537$. 
19.5 How to Draw a Regular 17-Gon

Many constructions for the regular 17-gon have been devised, the earliest published being that of Huguenin (see Klein, 1913) in 1803. For several of these constructions there are proofs of their correctness which use only synthetic geometry (ordinary Euclidean geometry without coordinates). A series of papers giving a construction for the regular 257-gon was published by F.J. Richelot (1832) under one of the longest titles I have ever seen. Bell (1965) tells of an overly zealous research student being sent away to find a construction for the 65537-gon, and reappearing with one 20 years later. This story, though apocryphal, is not far from the truth; Professor Hermes of Lingen spent 10 years on the problem, and his manuscripts are still preserved at Göttingen.

One way to construct a regular 17-gon is to follow faithfully the above theory, which in fact provides a perfectly definite construction after a little extra calculation. With ingenuity it is possible to shorten the work. The construction that we now describe is taken from Hardy and Wright (1962).

Our immediate object is to find radical expressions for the zeros of the polynomial

\[ \frac{t^{17} - 1}{t - 1} = t^{16} + \cdots + t + 1 \quad (19.1) \]

over \( \mathbb{C} \). Let

\[ \theta = \frac{2\pi}{17} \]

\[ \varepsilon_k = e^{k\theta} = \cos k\theta + i \sin k\theta \]

The zeros of equation (19.1) in \( \mathbb{C} \) are then \( \varepsilon_1, \ldots, \varepsilon_{16} \).

The powers of 3 reduced mod 17 are:

| \( m \) | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
|-------|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|
| \( 3^m \) | 1 | 3 | 9 | 10 | 13 | 5 | 15 | 11 | 16 | 8 | 7 | 4 | 12 | 2 | 6 |

Define

\[ x_1 = \varepsilon_1 + \varepsilon_9 + \varepsilon_{13} + \varepsilon_{15} + \varepsilon_8 + \varepsilon_4 + \varepsilon_2 \]

\[ x_2 = \varepsilon_3 + \varepsilon_{10} + \varepsilon_5 + \varepsilon_{11} + \varepsilon_{14} + \varepsilon_{12} + \varepsilon_6 \]

\[ y_1 = \varepsilon_1 + \varepsilon_{13} + \varepsilon_{16} + \varepsilon_4 \]

\[ y_2 = \varepsilon_9 + \varepsilon_{15} + \varepsilon_8 + \varepsilon_2 \]

\[ y_3 = \varepsilon_3 + \varepsilon_5 + \varepsilon_{14} + \varepsilon_{12} \]

\[ y_4 = \varepsilon_{10} + \varepsilon_{11} + \varepsilon_7 + \varepsilon_6 \]

Now

\[ \varepsilon_k + \varepsilon_{17-k} = 2 \cos k\theta \quad (19.2) \]
for \( k = 1, \ldots, 16 \), so

\[
\begin{align*}
x_1 &= 2(\cos \theta + \cos 8\theta + \cos 4\theta + \cos 2\theta) \\
x_2 &= 2(\cos 3\theta + \cos 7\theta + \cos 5\theta + \cos 6\theta) \\
y_1 &= 2(\cos \theta + \cos 4\theta) \\
y_2 &= 2(\cos 8\theta + \cos 2\theta) \\
y_3 &= 2(\cos 3\theta + \cos 5\theta) \\
y_4 &= 2(\cos 7\theta + \cos 6\theta)
\end{align*}
\]

Equation (19.1) implies that

\[x_1 + x_2 = -1\]

Now (19.3) and the identity

\[2 \cos m\theta \cos n\theta = \cos(m + n)\theta + \cos(m - n)\theta\]

imply that

\[x_1 x_2 = 4(x_1 + x_2) = -4\]

using (19.2). Hence \( x_1 \) and \( x_2 \) are zeros of the quadratic polynomial

\[t^2 + t - 4\]  \( (19.4)\)

Further, \( x_1 > 0 \) so that \( x_1 > x_2 \). By further trigonometric expansions,

\[y_1 + y_2 = x_1 \quad y_1 y_2 = -1\]

and \( y_1, y_2 \) are the zeros of

\[t^2 - x_1 t - 1\]  \( (19.5)\)

Further, \( y_1 > y_2 \). Similarly, \( y_3 \) and \( y_4 \) are the zeros of

\[t^2 - x_2 t - 1\]  \( (19.6)\)

and \( y_3 > y_4 \). Now

\[2 \cos \theta + 2 \cos 4\theta = y_1\]

\[4 \cos \theta \cos 4\theta = 2\cos 5\theta + 2\cos 3\theta = y_3\]

so

\[\tau_1 = 2 \cos \theta \quad \tau_2 = 2 \cos 4\theta\]
are the zeros of
\[ t^2 - y_1 t + y_3 \]  
(19.7)
and \( z_1 > z_2 \).

Solving the series of quadratics (19.4 to 19.7) and using the inequalities to decide which zero is which, we obtain

\[
\cos \theta = \frac{1}{16} \left( -1 + \sqrt{17} + \sqrt{34 - 2\sqrt{17}} \right.
+ \sqrt{68 + 12\sqrt{17} - 16\sqrt{34 + 2\sqrt{17} - 2(1 - \sqrt{17})\sqrt{34 - 2\sqrt{17}}} \right)
\]

where the square roots are the positive ones.

From this we can deduce a geometric construction for the 17-gon by constructing the relevant square roots. By using greater ingenuity it is possible to obtain an aesthetically more satisfying construction. The following method (Figure 19.9) is due to Richmond (1893).

Let \( \phi \) be the smallest positive acute angle such that \( 4\phi = 4 \). Then \( \phi, 2\phi \), and \( 4\phi \) are all acute. Expression (19.4) can be written

\[ t^2 + 4t \cot 4\phi - 4 \]

whose zeros are

\[ 2 \tan 2\phi \quad -2 \cot 2\phi \]

Hence

\[ x_1 = 2 \tan 2\phi \quad x_2 = -2 \cot 2\phi \]

Figure 19.9: Construction for a regular 17-gon.
From this it follows that

\[ y_1 = \tan \left( \phi + \frac{\pi}{4} \right) \quad y_2 = \tan \left( \phi - \frac{\pi}{4} \right) \quad y_3 = \tan \phi \quad y_4 = -\cot \phi \]

Then

\[ \begin{align*}
2(\cos 3\theta + \cos 5\theta) &= -\tan \phi \\
4 \cos 3\theta \cos 5\theta &= \tan \left( \phi - \frac{\pi}{4} \right)
\end{align*} \tag{19.8} \]

Now (Figure 19.9) let OA, OB be two perpendicular radii of a circle. Make \(\text{OI} = \frac{1}{4} \text{OB}\) and \(\angle \text{OIE} = \frac{1}{4} \angle \text{OIA}\). Find F on AO produced to make \(\angle \text{EIF} = \frac{\pi}{4}\). Let the circle on AF as diameter cut OB in K, and let the circle centre E through K cut OA in N_3 and N_5 as shown. Draw N_3P_3 and N_5P_5 perpendicular to OA. Then \(\angle \text{OIA} = 4\phi\) and \(\angle \text{OIE} = \phi\). Also,

\[ 2(\cos \angle \text{AOP}_3 + \cos \angle \text{AOP}_5) = 2\frac{\text{ON}_3 - \text{ON}_5}{\text{OA}} \]

\[ = 4 \frac{\text{OE}}{\text{OA}} + \frac{\text{OE}}{\text{OI}} = \tan \phi \]

and

\[ 4 \cos \angle \text{AOP}_3 \cos \angle \text{AOP}_5 = -4 \frac{\text{ON}_3 \times \text{ON}_5}{\text{OA} \times \text{OA}} \]

\[ = -4 \frac{\text{OK}^2}{\text{OA}^2} \]

\[ = -4 \frac{\text{OF}}{\text{OA}} \]

\[ = -\frac{\text{OF}}{\text{OI}} = \tan \left( \phi - \frac{\pi}{4} \right) \]

Comparing these with Equation (19.8) we see that

\(\angle \text{AOP}_3 = 3\theta \quad \angle \text{AOP}_5 = 5\theta\)

Hence A, P_3, P_5 are the zeroth, third, and fifth vertices of a regular 17-gon inscribed in the given circle. The other vertices are now easily found.

---

**Exercises**

19.1 Using only the operations ruler and compasses, show how to draw a parallel to a given line through a given point.
19.2 Verify the following approximate constructions for regular \( n \)-gons found by Oldroyd (1955):

a. 7-gon. Construct \( \cos^{-1} \frac{4 + \sqrt{5}}{10} \) giving an angle of approximately \( 2\pi/7 \).

b. 9-gon. Construct \( \cos^{-1} \frac{5\sqrt{3} - 1}{10} \).

c. 11-gon. Construct \( \cos^{-1} \frac{8}{9} \) and \( \cos^{-1} \frac{1}{2} \) and take their difference.

d. 13-gon. Construct \( \tan^{-1} 1 \) and \( \tan^{-1} \frac{4 + \sqrt{5}}{20} \) and take their difference.

19.3 Show that for \( n \) odd the only known constructible \( n \)-gons are precisely those for which \( n \) is a divisor of \( 2^{32} - 1 = 4294967295 \).

19.4 Work out the approximate size of \( F_{382449} \), which is known to be composite. Explain why it is no easy task to find factors of Fermat numbers.

19.5 Use the equations

\[ 641 = 5^4 + 2^4 = 5 \cdot 2^7 + 1 \]

to show that 641 divides \( F_5 \).

19.6 Show that

\[ F_{n+1} = 2 + F_n F_{n-1} \ldots F_0 \]

and deduce that if \( m \neq n \), then \( F_m \) and \( F_n \) are coprime. Hence show that there are infinitely many prime numbers.

19.7 List the values of \( n \leq 100 \) for which the regular \( n \)-gon can be constructed by ruler and compasses.

19.8 Verify the following construction for the regular pentagon.

Draw a circle centre O with two perpendicular radii OP₀, OB. Let D be the midpoint of OB, join P₀D. Bisect \( \angle ODP_0 \) cutting OP₀ at N. Draw NP₁ perpendicular to OP₀ cutting the circle at P₁. Then P₀ and P₁ are the zeroth and first vertices of a regular pentagon inscribed in the circle.

19.9* Discuss the construction of regular polygons using a ruler, compasses, and an angle trisector. (For example, 9-gons or 13-gons are then constructible. Use the trigonometric solution of cubic equations.)

19.10 Euclid’s construction for an isosceles triangle with angles \( 4\pi/5, 4\pi/5, 2\pi/5 \) depends on constructing the so-called golden section: that is, to construct a given straight line so that the rectangle contained by the whole and one of the segments is equal to the square on the other segment. The Greek term was “extreme and mean ratio.” In Book 2 Proposition 11 of the Elements Euclid solves this problem as in Figure 19.10.
Figure 19.10: Cutting a line in extreme and mean ratio.

Let AB be the given line. Make ABDC a square. Bisect AC at E, and make EF = BE. Now find H such that AH = AF. Then the square on AH has the same area as the rectangle with sides AB and BH, as required.
Prove that Euclid was right.

19.11 Mark the following true or false.

a. \(2^n + 1\) cannot be prime unless \(n\) is a power of 2.
b. If \(n\) is a power of 2, then \(2^n + 1\) is always prime.
c. The regular 771-gon is constructible using ruler and compasses.
d. The regular 768-gon is constructible using ruler and compasses.
e. The regular 51-gon is constructible using ruler and compasses.
f. The regular 25-gon is constructible using ruler and compasses.
g. For an odd prime \(p\), the regular \(p^2\)-gon is never constructible using ruler and compasses.
h. If \(n\) is an integer > 0, then a line of length \(\sqrt{n}\) can always be constructed using ruler and compasses.
i. If \(n\) is an integer > 0, then a line of length \(\sqrt[3]{n}\) can always be constructed using ruler and compasses.
j. A point whose coordinates lie in a normal extension of \(\mathbb{Q}\) whose degree is a power of 2 is constructible using ruler and compasses.
k. If \(p\) is a prime, then \(p^2 - 1\) is irreducible over \(\mathbb{Q}\).
Chapter 20

Finite Fields

Fields that have finitely many elements play important parts in many branches of mathematics: number theory, group theory, projective geometry, and so on. They also have practical applications, especially to the coding of digital communications, see Lidl and Niederreiter (1986), and, especially for the history, Thompson (1983).

The most familiar examples of such fields are the fields $\mathbb{Z}_p$ for prime $p$, but these are not all. In this chapter we give a complete classification of all finite fields. It turns out that a finite field is uniquely determined up to isomorphism by the number of elements it contains, this number being a power of a prime, and for every prime $p$ and integer $n > 0$ there exists a field with $p^n$ elements. All these facts were discovered by Galois, though not in this terminology.

20.1 Structure of Finite Fields

We begin by proving the second of these three statements.

**Theorem 20.1**

If $F$ is a finite field, then $F$ has characteristic $p > 0$, and the number of elements of $F$ is $p^n$ where $n$ is the degree of $F$ over its prime subfield.

**Proof** Let $P$ be the prime subfield of $F$. Here $P$ is not isomorphic to $\mathbb{Q}$ since $\mathbb{Q}$ is infinite, so $P$ is isomorphic to $\mathbb{Z}_p$ for some prime $p$ by Theorem 16.9, so $F$ has characteristic $p$. By Theorem 16.1, $F$ is a vector space over $P$. This vector space has finitely many elements, so must be finite-dimensional. Hence $[F : P] = n$ is finite. Let $x_1, \ldots, x_n$ be a basis for $F$ over $P$. Every element of $F$ is uniquely expressible in the form

$$\lambda_1 x_1 + \cdots + \lambda_n x_n$$

where $\lambda_1, \ldots, \lambda_n \in P$. Each $\lambda_j$ may be chosen in $p$ ways since $|P| = p$, hence there are $p^n$ such expressions. Therefore, $|F| = p^n$. \qed

Thus there do not exist fields with 6, 10, 12, 14, 18, 20, \ldots elements. Notice the contrast with group theory, where there exist groups of any given order.
However, there exist nonisomorphic groups with equal orders. To show that this cannot happen for finite fields, we recall the Frobenius map, Definition 17.15, which maps $x$ to $x^p$ and is an automorphism when the field is finite by Lemma 17.14. We use the Frobenius automorphism to establish a basic uniqueness theorem for finite fields:

**Theorem 20.2**

Let $p$ be any prime number and let $p = p^n$ where $n$ is any integer $> 0$. A field $F$ has $q$ elements if and only if it is a splitting field for $f(t) = t^q - t$ over the prime subfield $P \cong \mathbb{Z}_p$ of $F$.

**Proof** Suppose that $|F| = q$. The set $F \setminus \{0\}$ forms a group under multiplication, of order $q - 1$, so if $0 \neq x \in F$, then $x^{q-1} = 1$. Hence $x^q - x = 0$. Since $0^q - 0 = 0$, every element of $F$ is a zero of $t^q - t$, so $f(t)$ splits in $F$. Since the zeros of $f$ exhaust $F$, they certainly generate it, so $F$ is a splitting field for $f$ over $P$.

Conversely, let $K$ be a splitting field for $f$ over $\mathbb{Z}_p$. Since $Df = -1$, which is prime to $f$, all the zeros of $f$ in $K$ are distinct, so $f$ has exactly $q$ zeros. Suppose $x$ and $y$ are zeros of $f$. Then $x^q = x^{p^n} = \phi^n(x)$ where $\phi$ is the Frobenius automorphism, so $\phi^n$ is also an automorphism. Therefore,

\[
(xy)^q - xy = x^q y^q - xy = xy - xy = 0
\]

\[
(x + y)^q - (x + y) = x^q + y^q - (x + y) = (x + y) - (x + y) = 0
\]

\[
(x^{-1})^q - x^{-1} = x^{-q} - x^{-1} = x^{-1} - x^{-1} = 0
\]

Hence the set of zeros of $f$ in $K$ is a field, which must, therefore, be the whole splitting field $K$. Therefore, $|K| = q$.

Since splitting fields exist and are unique up to isomorphism, we deduce a complete classification of finite fields:

**Theorem 20.3**

A finite field has $q = p^n$ elements where $p$ is a prime number and $n$ is a positive integer. For each such $q$ there exists, up to isomorphism, precisely one field with $q$ elements, which can be constructed as a splitting field for $t^q - t$ over $\mathbb{Z}_p$.

**Definition 20.4** The Galois Field $\mathbb{GF}(q)$ is the unique field with $q$ elements.

---

### 20.2 The Multiplicative Group

The above classification of finite fields, although a useful result in itself, does not give any detailed information on their deeper structure. There are many questions we might ask: What are the subfields? How many are there? What are the Galois groups?
20.2 The Multiplicative Group

We content ourselves with proving one important theorem, which gives the structure of the multiplicative group $F \setminus \{0\}$ of any finite field $F$. First, we need to know a little more about abelian groups.

**Definition 20.5** The exponent $e(G)$ of a finite group $G$ is the least common multiple of the orders of the elements of $G$.

Clearly, $e(G)$ divides the order of $G$. In general, $G$ need not possess an element of order $e(G)$; for example, if $G = \mathbb{Z}_6$, then $e(G) = 6$, but $G$ has no element of order 6. Abelian groups are better behaved in this respect:

**Lemma 20.6**
Any finite abelian group $G$ contains an element of order $e(G)$.

**Proof** Let $e = e(G) = p_1^{\alpha_1} \cdots p_n^{\alpha_n}$ where the $p_j$ are distinct primes and $\alpha_j \geq 1$. Then $G$ must possess elements $g_j$ whose orders are divisible by $p_j^{\alpha_j}$ from the definition of $e(G)$. Then a suitable power $a_j$ of $g_j$ has order $p_j^{\alpha_j}$. Define

$$g = a_1 a_2 \cdots a_n$$

Suppose that $g^m = 1$ where $m \geq 1$. Then

$$a_j^m = a_1^{-m} \cdots a_{j-1}^{-m} a_j^{-m} \cdots a_n^{-m}$$

So if

$$q = p_1^{\alpha_1} \cdots p_j^{-1} p_{j+1}^{\alpha_{j+1}} \cdots p_n^{\alpha_n}$$

then $a_j^{mq} = 1$. But $q$ is prime to the order of $a_j$, so $p_j^{\alpha_j}$ divides $m$. Hence $e$ divides $m$. But, clearly, $g^e = 1$. Hence $g$ has order $e$, which is what we want.

**Corollary 20.7**
If $G$ is a finite abelian group such that $e(G) = |G|$, then $G$ is cyclic.

**Proof** The element $g$ constructed above generates $G$.

We can apply this corollary immediately.

**Theorem 20.8**
If $G$ is a finite subgroup of the multiplicative group $K \setminus \{0\}$ of a field $K$, then $G$ is cyclic.

**Proof** Since multiplication in $K$ is commutative, $G$ is an abelian group. Let $e = e(G)$. For any $x \in G$ we have $x^e = 1$, so that $x$ is a zero of the polynomial $t^e - 1$.
over $K$. By Theorem 3.28 (generalized) there are at most $e$ zeros of this polynomial, so $|G| \leq e$. But $e \leq |G|$, hence $e = |G|$; by Corollary 20.7, $G$ is cyclic.

**COROLLARY 20.9**

The multiplicative group of a finite field is cyclic.

Therefore, for any finite field $F$ there is at least one element $x$ such that every nonzero element of $F$ is a power of $x$. We give two examples.

**Examples 20.10**

1. The field $\mathbb{GF}(11)$. The powers of 2, in order, are

$$1, 2, 4, 8, 5, 10, 9, 7, 3, 6, 1$$

so 2 generates the multiplicative group. On the other hand, the powers of 4 are

$$1, 4, 5, 9, 3, 1$$

so 4 does not generate the group.

2. The field $\mathbb{GF}(25)$. This can be constructed as a splitting field for $t^2 - 2$ over $\mathbb{Z}_5$, since $t^2 - 2$ is irreducible and of degree 2. We can, therefore, represent the elements of $\mathbb{GF}(25)$ in the form $a + b\alpha$ where $\alpha^2 = 2$. There is no harm in writing $\alpha = \sqrt{2}$. By trial and error we are led to consider the element $2 + \sqrt{2}$. Successive powers of this are

$$1, 2 + \sqrt{2}, 1 + 4\sqrt{2}, 4\sqrt{2}, 3 + 3\sqrt{2}, 2 + 4\sqrt{2}, 2$$

$$4 + 2\sqrt{2}, 2 + 3\sqrt{2}, 3\sqrt{2}, 1 + \sqrt{2}, 4 + 3\sqrt{2}, 4$$

$$3 + 4\sqrt{2}, 4 + \sqrt{2}, \sqrt{2}, 2 + 2\sqrt{2}, 3 + \sqrt{2}, 3$$

$$1 + 3\sqrt{2}, 3 + 2\sqrt{2}, 2\sqrt{2}, 4 + 4\sqrt{2}, 1 + 2\sqrt{2}, 1$$

Hence $2 + \sqrt{2}$ generates the multiplicative group.

There is no known procedure for finding a generator other than enlightened trial and error. Fortunately, the existence of a generator is usually sufficient information.

---

**20.3 Application to Solitaire**

Finite fields have an unexpected application to the recreational pastime of solitaire (de Bruijn, 1972). Solitaire is played on a board with holes arranged like Figure 20.1. A peg is placed in each hole except the centre one, and play proceeds by jumping any peg horizontally or vertically over an adjacent peg into an empty hole; the peg that is jumped over is removed. The player's objective is to remove all pegs except one.
which — traditionally — is the peg that occupies the central hole. Can it be another hole? Experiment shows that it can, but suggests that the final peg cannot occupy any hole. Which holes are possible?

De Bruijn's idea is to use the field \( \mathbb{GF}(4) \), whose addition and multiplication tables are given in Exercise 16.6, in terms of elements 0, 1, \( \alpha \), \( \beta \). Consider the holes as a subset of the integer lattice \( \mathbb{Z}^2 \), with the origin (0, 0) at the centre and the axes horizontal and vertical as usual. If \( X \) is a set of pegs, define

\[
A(X) = \sum_{(x,y) \in X} \alpha^{x+y} \quad B(X) = \sum_{(x,y) \in X} \alpha^{x-y}
\]

Observe that if a legal move changes \( X \) to \( Y \), then \( A(Y) = A(X) \), \( B(Y) = B(X) \). This follows easily from \( \alpha^2 + \alpha + 1 = 0 \), which in turn follows from the tables. Thus the pair \( (A(X), B(X)) \) is invariant under any sequence of legal moves.

The starting position \( X \) has \( A(X) = B(X) = 1 \). Therefore, any position \( Y \) that arises during the game must satisfy \( A(Y) = B(Y) = 1 \). If the game ends with a single peg on \( (x, y) \), then \( \alpha^{x+y} = \alpha^{x-y} = 1 \). Now \( \alpha^3 = 1 \), so \( x + y, x - y \) are multiples of 3; therefore, \( x, y \) are multiples of 3. Thus the only possible end positions are \((-3, 0), (0, -3), (0, 0), (0, 3), (3, 0)\). Experiment (by symmetry, only \( (0, 0) \), the traditional finish, and \((3, 0)\) need be attempted; moreover, the same penultimate move must lead to both, depending on which peg is moved) shows that all five of these positions can be obtained by a series of legal moves.

---

**Exercises**

20.1 For which of the following values of \( n \) does there exist a field with \( n \) elements?

\[
1, 2, 3, 4, 5, 6, 17, 24, 312, 65536, \\
65537, 83521, 103823, 2^{13466917} - 1
\]

(*Hint*: See "Mersenne primes" under Internet References.)
20.2 Construct fields having 8, 9, and 16 elements.

20.3 Let \( \phi \) be the Frobenius automorphism of \( \mathbb{GF}(p^n) \). Find the smallest value of \( m > 0 \) such that \( \phi^m \) is the identity map.

20.4 Show that the subfields of \( \mathbb{GF}(p^n) \) are isomorphic to \( \mathbb{GF}(p^r) \) where \( r \) divides \( n \), and there exists a unique subfield for each such \( r \).

20.5 Show that the Galois group of \( \mathbb{GF}(p^n) : GF(p) \) is cyclic of order \( n \), generated by the Frobenius automorphism \( \phi \). Show that for finite fields the Galois correspondence is a bijection, and find the Galois groups of

\[
\mathbb{GF}(p^n) : \mathbb{GF}(p^m)
\]

whenever \( m \) divides \( n \).

20.6 Are there any composite numbers \( r \) that divide all the binomial coefficients \( \binom{r}{s} \) for \( 1 \leq s \leq r - 1 \)?

20.7 Find generators for the multiplicative groups of \( \mathbb{GF}(n) \) when \( n = 8, 9, 13, 17, 19, 23, 29, 31, 37, 41, \) and \( 49 \).

20.8 Show that the additive group of \( \mathbb{GF}(p^n) \) is a direct product of \( n \) cyclic groups of order \( p \).

20.9 By considering the field \( \mathbb{Z}_2(t) \), show that the Frobenius monomorphism is not always an automorphism.

0.10* For which values of \( n \) does \( S_n \) contain an element of order \( e(S_n) \)? (Hint: Use the cycle decomposition to estimate the maximum order of an element of \( S_n \), and compare this with an estimate of \( e(S_n) \). You may need estimates on the size of the \( n \)th prime: for example, Bertrand's Postulate, which states that the interval \([n, 2n]\) contains a prime for any integer \( n \geq 1 \).

0.11* Prove that in a finite field every element is a sum of two squares.

20.12 Mark the following true or false.

a. There is a finite field with 124 elements.

b. There is a finite field with 125 elements.

c. There is a finite field with 126 elements.

d. There is a finite field with 127 elements.

e. There is a finite field with 128 elements.

f. The multiplicative group of \( \mathbb{GF}(19) \) contains an element of order 3.

g. \( \mathbb{GF}(2401) \) has a subfield isomorphic to \( \mathbb{GF}(49) \).

h. Any monomorphism from a finite field to itself is an automorphism.

i. The additive group of a finite field is cyclic.
Chapter 21

Circle Division

To halt the story of regular polygons at the stage of ruler-and-compass constructions would leave a small but significant gap in our understanding of the solution of polynomial equations by radicals. Our definition of **radical extension** involves a slight cheat, which becomes evident if we ask what the expression of a root of unity looks like. Specifically, what does the radical expression of the primitive 11th root of unity

\[ \zeta_{11} = \cos \frac{2\pi}{11} + i \sin \frac{2\pi}{11} \]

look like?

As the theory stands, the best we can offer is

\[ \sqrt[11]{1} \]  

(21.1)

which is not terribly satisfactory, because the obvious interpretation of \( \sqrt[11]{1} \) is 1, not \( \zeta_{11} \). Gauss’s theory of the 17-gon hints that there might be a more impressive answer. In place of \( \sqrt[11]{1} \) Gauss has a marvellously complicated system of nested square roots:

\[
\cos \frac{2\pi}{17} = \frac{1}{16} \left( -1 + \sqrt{17} + \sqrt{34 - 2\sqrt{17}} + \sqrt{68 + 12\sqrt{17} - 16\sqrt{34 + 2\sqrt{17} - 2(1 - \sqrt{17})\sqrt{34 - 2\sqrt{17}}} \right)
\]

with a similar expression for \( \sin \frac{2\pi}{17} \), and hence an even more impressive formula for \( \zeta_{17} = \cos \frac{2\pi}{17} + i \sin \frac{2\pi}{17} \).

Can something similar be done for the 11th root of unity? For all roots of unity? The answer to both questions is “yes,” and we are getting the history back to front, because Gauss gave that answer as part of his work on the 17-gon. Indeed, Vandermonde came very close to the same answer 25 years earlier, in 1771, and in particular he managed to find an expression by radicals for \( \zeta_{11} \) that is less disappointing than (21.1). He, in turn, built on the epic investigations of Lagrange.

The technical term for this area is **cyclootomy**, from the Greek for circle cutting. In particular, pursuing Gauss’s and Vandermonde’s line of enquiry will lead us to some fascinating properties of the **cyclotomic polynomial** \( \Phi_d(i) \), which is the minimal polynomial over \( \mathbb{Q} \) of a primitive \( d \)th root of unity in \( \mathbb{C} \).
21.1 Nontrivial Radicals

Of course, we can solve the entire problem at a stroke if we define \( \sqrt[n]{1} \) to be the primitive \( n \)th root of unity

\[
\cos \frac{2\pi}{n} + i \sin \frac{2\pi}{n}
\]

instead of defining it to be 1. In a sense, this is what Definition 15.2 does. However, there is a better solution, as we shall see. What makes the above interpretation of \( \sqrt[n]{1} \) unsatisfactory? Consider the typical case of \( \zeta_{17} = \sqrt[17]{1} \). The minimal polynomial of \( \zeta_{17} \) is not \( t^{17} - 1 \), as the notation \( \sqrt[17]{1} \) suggests; instead, it has degree 16, being equal to

\[
t^{16} + t^{15} + \cdots + t + 1
\]

It would be reasonable to seek to determine the zeros of this 16th degree equation using radicals of degree 16 or less. But a 17th root seems rather out of place, especially since we know from Gauss that in this case (nested) square roots are enough.

However, that is a rather special example. What about other \( n \)th roots of unity?

When \( n = 2 \), the primitive square root of unity is \(-1\). This lies in \( \mathbb{Q} \), so no radicals are needed.

When \( n = 3 \), the primitive cube roots of unity are solutions of the quadratic equation

\[
t^2 + t + 1 = 0
\]

and so are of the form \( \omega, \omega^2 \) where

\[
\omega = -\frac{1}{2} + i \frac{\sqrt{3}}{2}
\]

involving only a square root.

When \( n = 4 \), a primitive 4th root of unity is \( i \), which again can be represented using only a square root, since \( i = \sqrt{-1} \).

When \( n = 5 \), we have to solve

\[
t^4 + t^3 + t^2 + t + 1 = 0
\]

(21.2)

We know from Chapter 18 that any quartic can be solved by radicals; indeed, only square and cube roots are required (in part because \( \sqrt[\sqrt{\cdot}] = \sqrt[\cdot]{\sqrt{\cdot}} \)). But we can do better. There is a standard trick that applies to equations of even degree that are palindromic—the list of coefficients is symmetric about the central term. We encountered this trick in Exercises 15.4 and 15.5. Express the equations in terms of a new variable

\[
u = t + \frac{1}{t}
\]

(21.3)
21.1 Nontrivial Radicals

Then

\[ u^2 = t^2 + 2 + \frac{2}{t^2} \]
\[ u^3 = t^3 + 3t + \frac{3}{t} + \frac{2}{t^3} \]

and so on. Rewrite (21.2) by dividing by \( t^2 \):

\[ t^2 + t + 1 + \frac{1}{t} + \frac{1}{t^2} = 0 \]

which in terms of \( u \) becomes

\[ u^2 + u - 1 = 0 \]

which is quadratic in \( u \). Solving for \( u \):

\[ u = \frac{-1 \pm \sqrt{5}}{2} \]

Now we recover \( t \) from \( u \) by solving a second quadratic equation. From (21.3)

\[ t^2 - ut + 1 = 0 \]

so

\[ t = \frac{u \pm \sqrt{u^2 - 4}}{2} \]

Explicitly, we get four zeros:

\[ t = \frac{-1 \pm \sqrt{5} \pm \sqrt{-10 - 2\sqrt{5}}}{4} \]

with independent choices of the signs \( \pm \). So we can express primitive 5th roots of unity using nothing worse than square roots.

Continuing in this way, we can find a radical expression for a primitive 6th root of unity (it is \( -\omega \), a primitive 7th root of unity (use the \( t + 1/t \) trick to reduce to a cubic), a primitive 8th root of unity (\( \sqrt{i} \) is one possibility, \( 1+i\sqrt{2} \) is perhaps better), a primitive 9th root of unity (\( \sqrt[3]{\omega} \)), and a primitive 10th root of unity (\( -\zeta_5 \)). The first case that baffled mathematicians prior to 1771 was, therefore, the primitive 11th root of unity, which leads to a quintic if we try the \( t + 1/t \) trick. But in that year, Vandermonde
obtained the explicit radical expression

\[
\zeta_{11} = \frac{1}{5} \left[ \sqrt[3]{\frac{11}{4} \left( 89 + 25\sqrt{5} - 5\sqrt{-5} + 2\sqrt{5} - 45\sqrt{-5} - 2\sqrt{5} \right)} + \sqrt[3]{\frac{11}{4} \left( 89 + 25\sqrt{5} - 5\sqrt{-5} + 2\sqrt{5} - 45\sqrt{-5} - 2\sqrt{5} \right)} + \sqrt[3]{\frac{11}{4} \left( 89 + 25\sqrt{5} - 5\sqrt{-5} + 2\sqrt{5} + 45\sqrt{-5} - 2\sqrt{5} \right)} + \sqrt[3]{\frac{11}{4} \left( 89 - 25\sqrt{5} - 5\sqrt{-5} - 2\sqrt{5} + 45\sqrt{-5} - 2\sqrt{5} \right)} \right]
\]

Vandermonde stated that his method would work for any primitive \( n \)th root of unity, but he did not give a proof. That was supplied by Gauss in 1796, and it was published in 1801 in his *Disquisitiones Arithmeticae* (with a gap in the proof, see below). It is not known whether Gauss was aware of Vandermonde’s pioneering work.

---

**21.2 Fifth Roots Revisited**

Before proving a version of Gauss’s theorem on the representability of roots of unity by nontrivial radicals, it helps to have an example. We can explain Vandermonde’s approach in the simpler case \( n = 5 \), where explicit calculations are not too lengthy.

As before, we want to solve

\[ t^4 + t^3 + t^2 + t + 1 = 0 \]

by radicals. We know that the zeros are

\[ \zeta, \quad \zeta^2, \quad \zeta^3, \quad \zeta^4 \]

where \( \zeta = \cos \frac{2\pi}{5} + i \sin \frac{2\pi}{5} \). The exponents 1, 2, 3, 4 can be considered as elements of the multiplicative group of the field \( \mathbb{Z}_5 \). This group is of order 4, generated by the element 2. Indeed, modulo 5 the powers of 2 are

\[ 2^0 = 1, \quad 2^1 = 2, \quad 2^2 = 4, \quad 2^3 = 3 \quad (21.5) \]

Further, we know that

\[ \alpha_0 = \zeta + \zeta^2 + \zeta^4 + \zeta^3 = -1 \]

which we write in this strange order because that is the natural ordering of the powers of 2, starting from \( 2^0 = 1 \). Consider (rabbit out of hat) the number

\[ \alpha_1 = \zeta + i\zeta^2 - \zeta^4 - i\zeta^3 \]
and compute its fourth power. We find (suppressing some details) that

\[ \alpha_1^2 = (1 + 2i)(\zeta - \zeta^2 + \zeta^4 - \zeta^3) \]

so, squaring again,

\[ \alpha_1^4 = -15 + 20i \]

Therefore we can express \( \alpha_1 \) by radicals:

\[ \alpha_1 = \sqrt[4]{-15 + 20i} \]

We can play a similar game with

\[ \alpha_3 = \zeta - i\zeta^2 - \zeta^4 + i\zeta^3 \]

to get

\[ \alpha_3 = \sqrt[4]{-15 - 20i} \]

The calculation of \( \alpha_1^4 \) also draws attention to

\[ \alpha_2 = \zeta - \zeta^2 + \zeta^4 - \zeta^3 \]

and shows that \( \alpha_2^2 = 5 \), so

\[ \alpha_2 = \sqrt{5} \]

Summarizing:

\[ \begin{align*}
\alpha_0 &= \zeta + \zeta^2 + \zeta^4 + \zeta^3 = -1 \\
\alpha_1 &= \zeta + i\zeta^2 - \zeta^4 - i\zeta^3 = \sqrt[4]{-15 + 20i} \\
\alpha_2 &= \zeta - \zeta^2 + \zeta^4 - \zeta^3 = \sqrt{5} \\
\alpha_3 &= \zeta - i\zeta^2 - \zeta^4 + i\zeta^3 = \sqrt[4]{-15 - 20i}
\end{align*} \]

Thus we find four linear equations in \( \zeta, \zeta^2, \zeta^3, \zeta^4 \). These equations are independent, and we can solve them. In particular,

\[ \alpha_0 + \alpha_1 + \alpha_2 + \alpha_3 \]

is equal to

\[ \zeta(1 + 1 + 1 + 1) + \zeta^2(1 + i - 1 - i) + \zeta^4(1 - 1 + 1 - 1) + \zeta^3(1 - i - 1 + i) = 4\zeta \]

Therefore,

\[ \zeta = \frac{1}{4} \left( -1 - \sqrt{5} + \sqrt{\sqrt{-15 + 20i} + \sqrt{-15 - 20i}} \right) \]
This expression is superficially different from (21.4) but, in fact, the two are equivalent. Both use nothing worse than square roots.

This calculation is too remarkable to be mere coincidence. It must work out nicely because of some hidden structure. What lies behind it?

The general idea behind Vandermone's calculation, as isolated by Gauss, is the following. The multiplicative group \( \mathbb{Z}_5^* \) is cyclic of order 4, and the number 2 (modulo 5) is a generator. It has order 4 in \( \mathbb{Z}_5^* \). The complex number \( i \) is a primitive 4th root of unity, so \( i \) has order 4 in the multiplicative group of 4th roots of unity, namely, \( 1, i, -1, -i \). These two facts conspire to make the algebra work.

To see how, we apply a little Galois theory — a classic case of being wise after the event. The Galois group \( \Gamma \) of \( \mathbb{Q}(\zeta) : \mathbb{Q} \) has order 4, and comprises the \( \mathbb{Q} \)-automorphisms generated by the maps

\[
\rho_k : \zeta \mapsto \zeta^k
\]

for \( k = 1, 2, 3, 4 \). The group \( \Gamma \) is isomorphic to \( \mathbb{Z}_4^* \) by the map \( \rho_k \mapsto k(\text{mod } 5) \). Therefore, \( \rho_2 \) has order 4 in \( \Gamma \), hence generates \( \Gamma \), and \( \Gamma \) is cyclic of order 4.

The extension is normal, since it is a splitting field for an irreducible polynomial, and we are working over \( \mathbb{C} \) so the extension is separable. By the Galois correspondence, any rational function of \( \zeta \) that is fixed by \( \rho_2 \) is, in fact, a rational number.

Consider as a typical case the expression \( \alpha_1 \) above. Write this as

\[
\alpha_1 = \zeta + i \rho_2(\zeta) + i^2 \rho_2(\zeta^2) + i^3 \rho_2(\zeta^3)
\]

Then

\[
\rho_2(\alpha_1) = \rho_2(\zeta) + i \rho_2(\zeta^2) + i^2 \rho_2(\zeta^3) + i^3 \zeta
\]

since \( \rho_4(\zeta)^4 = \zeta \). Therefore,

\[
\rho_2(\alpha_1) = i^{-1} \alpha_1
\]

so

\[
\rho_2(\alpha_1^4) = (i^{-1} \alpha_1)^4 = \alpha_1^4
\]

Thus \( \alpha_1^4 \) lies in the fixed field of \( \rho_2 \), that is, the fixed field of \( \Gamma \), which is \( \mathbb{Q} \ldots \)

Hold it.

The idea is right, but the argument has a flaw. The explicit calculation shows that \( \alpha_1^4 = -15 + 20i \), which lies in \( \mathbb{Q}(i) \), not \( \mathbb{Q} \). What was the mistake? The problem is that \( \alpha_1 \) is not an element of \( \mathbb{Q}(\zeta) \). It belongs to the larger field \( \mathbb{Q}(\zeta)(i) \), which equals \( \mathbb{Q}(i, \zeta) \). So we have to do the Galois theory for that extension, not \( \mathbb{Q}(\zeta) : \mathbb{Q} \).

It is fairly straightforward to do this. Since 4 and 5 are coprime, the product \( \xi = i\zeta \) is a primitive 20th root of unity. Moreover, \( \xi^5 = i, \xi^{16} = \zeta \). Therefore, \( \mathbb{Q}(i, \zeta) = \mathbb{Q}(\xi) \). Since 20 is not prime, we do not know that this group is cyclic, so we have to work out its structure. In fact, it is the group of units \( \mathbb{Z}_{20}^* \) of the ring \( \mathbb{Z}_{20} \), which is
isomorphic to $\mathbb{Z}_2 \times \mathbb{Z}_4$, not $\mathbb{Z}_8$. By considering the tower of fields
\[ \mathbb{Q} \subseteq \mathbb{Q}(i) \subseteq \mathbb{Q}(\xi) \]
and using the structure of $\mathbb{Z}_{20}^*$, it can be shown that the Galois group of $\mathbb{Q}(\xi) : \mathbb{Q}(i)$ is the $\mathbb{Z}_4$ quotient group of $\mathbb{Z}_{20}^*$ generated by a $\mathbb{Q}(i)$-automorphism $\bar{p}_2$ that sends $\xi$ to $\xi^2$ and fixes $\mathbb{Q}(i)$. We prove a more general theorem in Theorem 21.3.

Having made the switch to $\mathbb{Q}(\xi)$, the above calculation shows that $\alpha_1^4$ lies in the fixed field of the Galois group $\Gamma(\mathbb{Q}(\xi) : \mathbb{Q}(i))$. This field is $\mathbb{Q}(i)$, because the extension is normal and separable. So without doing the explicit calculations, we can see in advance that $\alpha_1^4$ must lie in $\mathbb{Q}(i)$. The same goes for $\alpha_2^4$, $\alpha_3^4$, and (trivially) $\alpha_0^4$.

---

### 21.3 Vandermonde Revisited

Vandermonde was very competent, but a bit of a plodder; he did not follow up his idea in full generality, and thereby missed a major discovery. He could well have anticipated Gauss, possibly even Galois, if he had found a proof that his method was a completely general way to express roots of unity by nontrivial radicals, instead of just asserting that it was.

As preparation, we now establish Vandermonde’s main point about the primitive $i$th roots of unity. Any unproved assertions about Galois groups will be dealt with in the general case (see Section 21.4). Let $\zeta = \zeta_{11}$. Vandermonde started with the identity
\[ \zeta^{10} + \zeta^9 + \cdots + \zeta + 1 = 0 \]
and played the $u = \zeta + 1/\zeta$ trick to reduce the problem to a quintic, but with hindsight this step is not necessary and, if anything, makes the idea more obscure. Introduce a primitive 10th root of unity $\theta$, so that $\theta \zeta$ is a primitive 110th root of unity. Consider the field extension $\mathbb{Q}(\theta \zeta) : \mathbb{Q}$, which turns out to be of degree 10, with a cyclic Galois group of order 10 that is isomorphic to $\mathbb{Z}_{11}^*$. A generator for $\mathbb{Z}_{11}^*$ is readily found and turns out to be the number 2, whose successive powers are
\[ 1, 2, 4, 8, 5, 10, 9, 7, 3, 6 \]
Therefore, $\Gamma = \Gamma(\mathbb{Q}(\theta \zeta) : \mathbb{Q}(\theta))$ consists of the $\mathbb{Q}(\theta)$-automorphisms $\rho_k$, for $k = 1, \ldots, 10$, that map
\[ \zeta \mapsto \zeta^k \quad \theta \mapsto \theta \]
Let $l$ be any integer, $0 \leq l \leq 9$, and define
\[ \alpha_l = \zeta + \theta^l \zeta^2 + \theta^{2l} \zeta^4 + \cdots + \theta^{9l} \zeta^6 \]
\[ = \sum_{j=0}^{9} \theta^{jl} \zeta^{2j} \] (21.6)
Consider the effect of \( \rho_2 \), which sends \( \zeta \mapsto \zeta^2 \) and fixes \( \theta \). We have

\[
\rho_2(\alpha_t) = \sum_{j=0}^{9} \theta^{j+1} \zeta^{2j+1} = \theta^{-t} \alpha_t
\]

so

\[
\rho_2(\alpha_t^{10}) = \theta^{-10} \alpha_t^{10} = \alpha_t^{10}
\]

and \( \alpha_t^{10} \) lies in the fixed field of \( \Gamma \), which is \( \mathbb{Q}(\theta) \). Thus there is some polynomial \( f_t(\theta) \), of degree \( \leq 9 \) over \( \mathbb{Q} \), with

\[
\alpha_t^{10} = f_t(\theta)
\]

With effort, we can compute \( f_t(\theta) \) explicitly. Shortcuts help. At any rate,

\[
\alpha_t = \frac{\sqrt[10]{f_t(\theta)}}{} \quad (21.7)
\]

We already know how to express \( \theta \) by nontrivial radicals since it is a primitive 10th root of unity, so we have expressed \( \alpha_t \) by radicals; in fact, only square roots and fifth roots are needed, since \( \sqrt[10]{\theta} = \sqrt[4]{\sqrt[5]{\theta}} \) and fifth roots of unity require only square roots.

Finally, the 10 equations (21.6) for the \( \alpha_t \) can be interpreted as a system of 10 linear equations for the powers \( \zeta, \zeta^2, \ldots, \zeta^{10} \) over \( \mathbb{C} \). These equations are independent, and can be solved (explicitly). Indeed, using elementary properties of 10th roots of unity it can be shown that

\[
\zeta^{2j} = \frac{1}{10} \left( \sum_{i=0}^{9} \theta^{-j} \alpha_i \right)
\]

In particular,

\[
\zeta = \frac{1}{10} \left( \sum_{i=0}^{9} \alpha_i \right) = \frac{1}{10} \left( \sum_{i=0}^{9} \frac{\sqrt[10]{f_t(\theta)}}{} \right)
\]

Thus we have expressed \( \zeta_{11} \) in terms of radicals, using only square roots and fifth roots.

Vandermonde's answer also uses only square roots and fifth roots, and can be deduced from the above formula. Because he used a variant of the above strategy, his answer does not immediately look the same as ours, but it is equivalent. To go beyond Vandermonde, we must prove that his method works for all primitive \( n \)th roots of unity. This we now establish.

### 21.4 The General Case

First, we must define what we mean by a nontrivial radical expression. Recall from Definition 1 that the radial degree of the radical \( \sqrt[n]{\cdot} \) is \( n \), and define the radial degree of a radical expression to be the maximum radial degree of the radicals that appear in it.
21.4 The General Case

**Definition 21.1** A number \( \alpha \in \mathbb{C} \) has a nontrivial radical expression if \( \alpha \) belongs to a radical extension of \( \mathbb{Q} \) formed by successive adjunction of \( k \)-th roots, where \( k \) is less than or equal to the degree of the minimal polynomial of \( \alpha \) over \( \mathbb{Q} \).

This definition rules out \( \sqrt[3]{1} \) as a nontrivial radical expression for \( \zeta_{11} \), but it permits \( \sqrt{-1} \) as a nontrivial radical expression for \( i \), and \( \sqrt[3]{2} \) as a nontrivial radical expression for \( -1 \), \( \sqrt[3]{2} \).

Our aim is to prove a theorem that was effectively stated by Vandermonde and proved in full rigour (and greater generality, but we have to stop somewhere) by Gauss. The name "Vandermonde-Gauss Theorem" is not standard, but it ought to be, so we shall use it.

**Theorem 21.2 (Vandermonde-Gauss Theorem)**

*For any \( n \geq 1 \), any \( n \)-th root of unity has a nontrivial radical expression.*

The aim of this section is to prove the Vandermonde-Gauss Theorem. In fact, we prove something distinctly stronger (see Exercise 21.3). We prove the theorem by induction on \( n \). It is easy to see that the induction step reduces to the case where \( n \) is prime and the \( n \)-th root of unity concerned is, therefore, primitive because if \( n = rs \) is composite we can write it as \( n = pq \) where \( p \) is prime, and \( \sqrt[n]{q} \).

Let \( n = p \) be prime and focus attention on a primitive \( p \)-th root of unity \( \zeta_p \), which for simplicity we denote by \( \zeta \). In trigonometric terms,

\[
\zeta = \cos \frac{2\pi}{p} + i \sin \frac{2\pi}{p}
\]

but we do not actually use this formula.

We already know the minimal polynomial of \( \zeta \) over \( \mathbb{Q} \), from Lemma 19.13. It is

\[
m(t) = t^{p-1} + t^{p-2} + \cdots + t + 1 = \frac{t^p - 1}{t - 1}
\]

Let

\[
\theta = \cos \frac{2\pi}{p-1} + i \sin \frac{2\pi}{p-1}
\]

be a primitive \((p-1)\)-th root of unity. Since \( p-1 \) is composite (except when \( p = 2, 3 \)), the minimal polynomial of \( \theta \) over \( \mathbb{Q} \) is not equal to

\[
c(t) = t^{p-2} + t^{p-3} + \cdots + t + 1 = \frac{t^{p-1} - 1}{t - 1}
\]

but instead it is some irreducible divisor of \( c(t) \).
Circle Division

We work not with $\mathbb{Q}(\zeta) : \mathbb{Q}$, but with $\mathbb{Q}(\theta, \zeta) : \mathbb{Q}$. Since $p, p - 1$ are coprime, this extension is the same as

$$\mathbb{Q}(\theta \zeta) : \mathbb{Q}$$

where $\theta \zeta$ is a primitive $p(p - 1)$th root of unity. A general element of $\mathbb{Q}(\theta \zeta)$ can be written as a linear combination over $\mathbb{Q}(\theta)$ of the powers $\zeta, \zeta^2, \ldots, \zeta^{p-2}$. It is convenient to throw in $\zeta^{p-1}$ as well, but now we must always bear in mind the relation $1 + \zeta + \zeta^2 + \ldots + \zeta^{p-1} = 0$.

We base the deduction on the following result, which we prove in Section 21.6 to avoid technical distractions.

**THEOREM 21.3**

The Galois group of $\mathbb{Q}(\theta \zeta) : \mathbb{Q}(\theta)$ is cyclic of order $p - 1$. It comprises the $\mathbb{Q}(\theta)$-automorphisms of the form $\rho_j (j = 1, 2, \ldots, p - 1)$ where

$$\rho_j : \zeta \mapsto \zeta^j$$

$$\theta \mapsto \theta$$

The main technical issue in proving this theorem is that although we know that $\zeta, \zeta^2, \ldots, \zeta^{p-2}$ are linearly independent over $\mathbb{Q}$, we do not (yet) know that they are linearly independent over $\mathbb{Q}(\theta)$. Even Gauss omitted the proof of this fact from his discussion in the *Disquisitiones Arithmeticae*, but that may have been because to him it was obvious. He never published a proof of this particular fact, though he must have known one. So in a sense the first complete proof should probably be credited to Galois.

Assuming Theorem 21.3, we can follow Vandermonde's method in complete generality, using a few simple facts about roots of unity.

**PROOF OF THE VANDERMONDE-GAUSS THEOREM** We prove the theorem by induction on $n$. The cases $n = 1, 2$ are trivial since the roots of unity concerned are $1, -1$. As explained above, the induction step reduces to the case where $n$ is prime and the $n$th root of unity concerned is, therefore, primitive. Throughout the proof it helps to bear in mind the above examples when $n = 5, 11$.

We write $n = p$ to remind us that $n$ is prime. Let $\zeta$ be a primitive $p$th root of unity and let $\theta$ be a primitive $(p - 1)$th root of unity as above. Then $\theta \zeta$ is a primitive $p(p - 1)$th root of unity.

By Theorem 21.3, the Galois group of $\mathbb{Q}(\theta \zeta) : \mathbb{Q}$ is isomorphic to $\mathbb{Z}_p^*$, and is thus cyclic of order $p - 1$. It comprises the automorphisms $\rho_j$ for $j = 1, \ldots, p - 1$. Since $\mathbb{Z}_p^*$ is cyclic, there exists a generator $a$. That is, every $j \in \mathbb{Z}_p^*$ can be expressed as a power $j = a^t$ of $a$. Then $\rho_j = \rho_a^j$, so $\rho_a$ generates $\Gamma = \Gamma(\mathbb{Q}(\theta \zeta) : \mathbb{Q}(\theta))$.

By Theorem 21.3 and Proposition 17.18, $\mathbb{Q}(\theta \zeta) : \mathbb{Q}(\theta)$ is normal and separable, so in particular the fixed field of $\Gamma$ is $\mathbb{Q}(\theta)$ by Theorem 12.1(2). Since $\rho_a$ generates $\Gamma$, any element of $\mathbb{Q}(\theta \zeta)$ that is fixed by $\rho_a$ must lie in $\mathbb{Q}(\theta)$.
We construct elements fixed by \( \rho_a \) as follows. Define
\[
\alpha_l = \zeta + \theta^l \zeta^a + \theta^{2l} \zeta^a^2 + \ldots + \theta^{(p-2)l} \zeta^a^{p-2} = \sum_{j=0}^{p-2} \theta^{jl} \zeta^a^j
\]
for \( 0 \leq l \leq p - 2 \). Then
\[
\rho_a(\alpha_l) = \sum_{j=0}^{p-2} \theta^{jl} \zeta^a^{j+1} = \theta^{-l} \alpha_l
\]
Therefore,
\[
\rho_a(\alpha_l^{p-1}) = (\theta^{-l} \alpha_l)^{p-1} = (\theta^{p-1})^{-l} \alpha_l^{p-1} = 1 \cdot \alpha_l^{p-1} = \alpha_l^{p-1}
\]
so \( \alpha_l^{p-1} \) is fixed by \( \rho_a \), hence lies in \( \mathbb{Q}(\theta) \). Say,
\[
\alpha_l^{p-1} = \beta_l \in \mathbb{Q}(\theta)
\]
Therefore,
\[
\alpha_l = \sqrt[p-1]{\beta_l} \quad (0 \leq l \leq p - 2)
\]
Recall (Exercise 21.5) the following property of roots of unity:
\[
1 + \theta^l + \theta^{2l} + \ldots + \theta^{(p-2)l} = \begin{cases} p - 1 & \text{if } l = 0 \\ 0 & \text{if } 1 \leq l \leq p - 2 \end{cases}
\]
Therefore, from (21.8),
\[
\zeta = \frac{1}{p-1} [\alpha_0 + \alpha_1 + \ldots + \alpha_{p-2}]
\]
\[
= \frac{1}{p-1} \left[ \sqrt[p-1]{\beta_0} + \sqrt[p-1]{\beta_1} + \ldots + \sqrt[p-1]{\beta_{p-2}} \right]
\]
which expresses \( \zeta \) by radicals over \( \mathbb{Q}(\theta) \).

Now, \( \theta \) is a primitive \((p-1)\)th root of unity, so by induction \( \theta \) is a radical expression over \( \mathbb{Q} \) of maximum radical degree \( \leq p - 2 \). (Actually we can say more: if \( p > 2 \), then \( p - 1 \) is even, so the maximum radical degree is max(2, \((p-1)/2\)). Note that when \( p = 3 \) we require a square root, but \((p-1)/2 = 1 \) (see Exercise 21.3.) The same goes for each \( \beta_l \) since \( \beta_l \) is a polynomial in \( \theta \) with rational coefficients. Substituting the rational expressions in (21.9) we see that \( \zeta \) is a radical expression over \( \mathbb{Q} \) of maximum radical degree \( \leq p - 1 \). (Again, we can improve this to max(2, \((p-1)/2\)) for \( p > 2 \) (see Exercise 21.3).)

Therefore, in particular, (21.9) yields a nontrivial radical expression for \( \zeta \) according to the definition, and the Vandermonde-Gauss Theorem is proved.
21.5 Cyclotomic Polynomials

In order to fill in the technical gap we first need:

**Theorem 21.4**

Any two primitive $n$th roots of unity in $\mathbb{C}$ have the same minimal polynomial over $\mathbb{Q}$.

Before starting on the proof, some motivation will be useful. Consider the case $n = 12$. Let

$$\zeta = \zeta_{12} = \cos \frac{2\pi}{12} + i \sin \frac{2\pi}{12}$$

We can classify the $\zeta^d$ according to their minimal power $d$ such that $\zeta^d = 1$. That is, we consider when they are primitive $d$th roots of unity. It is easy to see that in this case the primitive $d$th roots of unity are:

- $d = 1 \quad 1$
- $d = 2 \quad \zeta^6 (= -1)$
- $d = 3 \quad \zeta^4, \zeta^8 (= \omega, \omega^2)$
- $d = 4 \quad \zeta^3, \zeta^9 (= i, -i)$
- $d = 6 \quad \zeta^2, \zeta^{10} (= -\omega, -\omega^2)$
- $d = 12 \quad \zeta, \zeta^5, \zeta^7, \zeta^{11}$

We can factorize $t^{12} - 1$ by grouping corresponding zeros:

$$t^{12} - 1 = (t - 1) \times$$

$$(t - \zeta^6) \times$$

$$(t - \zeta^4)(t - \zeta^8) \times$$

$$(t - \zeta^3)(t - \zeta^9) \times$$

$$(t - \zeta^2)(t - \zeta^{10}) \times$$

$$(t - \zeta)(t - \zeta^5)(t - \zeta^7)(t - \zeta^{11})$$

which simplifies to

$$t^{12} - 1 = (t - 1)(t + 1)(t^2 + t + 1)(t^2 + 1)(t^2 - t + 1)F(t)$$

where

$$F(t) = (t - \zeta)(t - \zeta^5)(t - \zeta^7)(t - \zeta^{11})$$

whose explicit form is not immediately obvious. One way to work out $F(t)$ is to use trigonometry (Exercise 21.4). The other is to divide $t^{12} - 1$ by all the other factors, which leads rapidly to

$$F(t) = t^4 - t^2 + 1$$
If we let $\Phi_d(t)$ be the factor corresponding to primitive $d$th roots of unity, we have proved that

$$t^{12} - 1 = \Phi_1 \Phi_2 \Phi_3 \Phi_4 \Phi_6 \Phi_{12}$$

Our computations show that every factor $\Phi_j$ lies in $\mathbb{Z}[t]$. In fact, it turns out that the factors are all irreducible over $\mathbb{Z}$. This is obvious in some cases, and follows by the usual trick with Eisenstein's Criterion in the others (Exercise 21.11). This calculation generalizes, as the following proof (eventually) shows.

**Proof of Theorem 4** Let $J = J_n$ be the set of all $n$th roots of unity in $\mathbb{C}$, primitive or not. Define a relation $\sim$ on $J$ by

$$\epsilon \sim \delta \iff m_\epsilon(t) = m_\delta(t)$$

where $m_\epsilon(t)$ is the minimum polynomial of $\epsilon$ over $\mathbb{Q}$, and similarly for $m_\delta(t)$. It is clear that $\sim$ is an equivalence relation, so it partitions $J$ into equivalence classes. Let $[\epsilon]$ denote the equivalence class of $\epsilon \in J$.

Over $\mathbb{C}$ there is a factorization

$$t^n - 1 = \prod_{\delta \in J} (t - \delta)$$

and $m_\epsilon(t) | t^n - 1$ and is monic, so we must have

$$m_\epsilon(t) = \prod_{\delta \in \epsilon} (t - \delta)$$

for some subset $K_\epsilon \subseteq J$.

Over $\mathbb{C}$, the linear polynomial $t - \epsilon$ divides $m_\epsilon(t)$, hence $t - \delta$ divides $m_\epsilon(t)$ for all $\delta \sim \epsilon$. Therefore, the equivalence class $[\epsilon]$ of $\epsilon$ is contained in $K_\epsilon$. In fact, these sets must be equal, for if $K_\epsilon$ contains any $\delta \not\sim \epsilon$, then both $m_\epsilon(t)$ and $m_\delta(t)$ are divisible by $t - \delta$. Since $\delta \not\sim \epsilon$ these polynomials are coprime over $\mathbb{Q}$, because they are distinct monic irreducibles over $\mathbb{Q}$, so there exist $a(t), b(t) \in \mathbb{Q}[t]$ such that

$$a(t)m_\epsilon(t) + b(t)m_\delta(t) = 1$$

Then $t - \delta$ divides $a(t)m_\epsilon(t) + b(t)m_\delta(t)$ over $\mathbb{C}$, but this is 1, a contradiction.

We have, therefore, proved that

$$m_\epsilon(t) = \prod_{\delta \in \epsilon} (t - \delta) = m_{[\epsilon]}(t)$$

say. Since the equivalence classes partition $J$,

$$t^n - 1 = \prod_{[\epsilon]} m_{[\epsilon]}(t)$$

(21.10)
Circle Division

where the $m_{[e]}(t)$ are monic irreducible polynomials over $\mathbb{Q}$. Thus (21.10) is the factorization of $t^n - 1$ into monic irreducibles over $\mathbb{Q}$, hence also (by Corollary 3.18 to Gauss’s Lemma) the factorization of $t^n - 1$ into monic irreducibles over $\mathbb{Z}$. In particular, each $m_{[e]}(t)$ lies in $\mathbb{Z}[t]$.

We claim that if $p$ is any prime that does not divide $n$, and $\varepsilon \in J$, then $\varepsilon \sim \varepsilon^p$. This step, which is not at all obvious, is the heart of the proof.

We prove the claim by contradiction. If it is false, then $m_{[e]}(t) \neq m_{[e]}(t)$. Define

$$k(t) = m_{[e]}(t^p) \in \mathbb{Z}[t]$$

so

$$k(\varepsilon) = m_{[e]}(\varepsilon^p) = 0$$

Therefore, $m_{[e]}(t)$ divides $k(t)$ in $\mathbb{Z}[t]$, so there exists $q(t) \in \mathbb{Z}[t]$ such that

$$m_{[e]}(t)q(t) = k(t)$$

Reduce coefficients modulo $p$ as in Section 3.5. Using bars to denote images modulo $p$,

$$\bar{m}_{[e]}(t)\bar{q}(t) = k(t) = \bar{m}_{[e]}(t^p) = \left(\bar{m}_{[e]}(t)\right)^p$$

since the Frobenius map is a monomorphism in characteristic $p$ by Lemma 17.14.

Therefore, $\bar{m}_{[e]}(t)$ and $\bar{m}_{[e]}(t)$ have a common zero in some extension field of $\mathbb{Z}_p$, so that

$$\bar{t}^n - 1 = \prod_{[e]} \bar{m}_{[e]}(t)$$

has a repeated zero in some extension field of $\mathbb{Z}_p$. By Lemma 9.13 (generalized), $\bar{t}^n - 1$ and its formal derivative have a common zero. However, the formal derivative of $\bar{t}^n - 1$ is $\bar{n}t^{n-1}$ and $\bar{n} \neq 0$ since $p \nmid n$. Now

$$\frac{t}{\bar{n}}(\bar{n}t^{n-1}) - \bar{t}^{n-1} - \bar{1}$$

so no such common zero exists (that is, $\bar{n}t^{n-1}$ and $\bar{t}^{n-1}$ are coprime). This contradiction shows that $\varepsilon^p \sim \varepsilon$.

It follows that $\varepsilon^u \sim \varepsilon$ for every $u = p_1 \ldots p_i$ where the $p_j$ are primes not dividing $n$. These $u$ are precisely the natural numbers that are prime to $n$, so modulo $n$ they form the group of units $\mathbb{Z}_n^*$.

For each divisor $d$ of $n$, let $J_d \subseteq J$ be the set of all primitive $d$th roots of unity. Then

$$J = \bigcup_{d \mid n} J_d$$

where $\bigcup$ indicates that the union is disjoint. Clearly,

$$J_d = \{\varepsilon^u : u \in \mathbb{Z}_n^*\}$$
for any \( \varepsilon \in J_d \), because \( p \mid n \) implies \( p \mid \frac{n}{d} \). Therefore, if \( \varepsilon \) is a primitive \( d \)th root of unity, \( J_d \subseteq [\varepsilon] \). Thus if \( \varepsilon, \delta \) are any two primitive \( d \)th roots of unity, then \( [\varepsilon] \cap [\delta] \neq \emptyset \). But equivalence classes are either equal or disjoint, so we have a contradiction. Therefore, \( J_d = [\varepsilon] \) for any \( \varepsilon \) that is a primitive \( d \)th root of unity.

We deduce that

\[
\Phi_d(t) = \prod_{\sigma \in J_d} (t - \sigma)
\]

is the minimal polynomial of any primitive \( d \)th root of unity. Therefore, any two primitive \( d \)th roots of unity have the same minimal polynomial, namely, \( \Phi_d(t) \), as required. \( \square \)

**Definition 21.5** The polynomial \( \Phi_d(t) \) is the \( d \)th cyclotomic polynomial over \( \mathbb{C} \).

**Corollary 21.6**
For all \( d \in \mathbb{N} \), the polynomial \( \Phi_d(t) \) lies in \( \mathbb{Z}[t] \) and is monic and irreducible.

---

### 21.6 The Technical Lemma

We can now fill in the technical gap in the proof of the Vandermonde-Gauss Theorem in Section 21.4.

**Theorem 21.7**
Let \( K \) be the splitting field of \( \Phi_n(t) \) over \( \mathbb{Q} \). Then the Galois group of the extension \( K : \mathbb{Q} \) is isomorphic to the group of units \( \mathbb{Z}_n^* \) of the ring \( \mathbb{Z}_n \).

**Proof** The zeros of \( \Phi_n(t) \) in \( \mathbb{C} \) are powers \( \zeta^a \) of a primitive \( n \)th root of unity \( \zeta \), where \( a \) ranges through the integers modulo \( n \) that are prime to \( n \).

Let \( \sigma \in \Gamma(K : \mathbb{Q}) \). The effect of \( \sigma \) is uniquely determined by \( \sigma(\zeta) \), and both \( \zeta \) and \( \sigma(\zeta) \) must have the same minimal polynomial over \( \mathbb{Q} \), namely, \( \Phi_n(t) \). Therefore, \( \sigma(\zeta) = \zeta^a \), where \( a \in \mathbb{Z}_n^* \).

Let \( \sigma_a \) be the map determined by a given \( a \in \mathbb{Z}_n^* \). By Proposition 11.4 (generalized), \( \sigma_a \) is a \( \mathbb{Q} \)-automorphism of \( K \), hence lies in the Galois group. Therefore, \( \Gamma(K : \mathbb{Q}) \) consists of precisely the maps \( \sigma_a \) for \( a \in \mathbb{Z}_n^* \). Now

\[
\sigma_a(\sigma_b(\zeta)) = (\zeta^b)^a = \zeta^{ab}
\]

so the map \( \sigma_a \mapsto a \) is an isomorphism between \( \Gamma(K : \mathbb{Q}) \) and \( \mathbb{Z}_n^* \). \( \square \)
21.7 More on Cyclotomic Polynomials

It seems a shame to stop without saying a little more about the cyclotomic polynomials.

Theorem 21.7 shows that the cyclotomic polynomial \( \Phi_n(t) \) is intimately associated with the ring \( \mathbb{Z}_n \) and its group of units \( \mathbb{Z}_n^* \), which we discussed briefly in Chapter 3. In particular, the order of this group is

\[ |\mathbb{Z}_n^*| = \phi(n) \]

where \( \phi \) is the Euler function, so \( \phi(n) \) is the number of integers \( a \), with \( 1 \leq a \leq n-1 \), such that \( a \) is prime to \( n \).

The most basic property of the cyclotomic polynomials is the identity

\[ t^n - 1 = \prod_{d|n} \Phi_n(t) \quad (21.11) \]

which is a direct consequence of their definition. We can use this identity recursively to compute \( \Phi_n(t) \). Thus

\[ \Phi_1(t) = t - 1 \]

so

\[ t^2 - 1 = \Phi_2(t)\Phi_1(t) \]

which implies that

\[ \Phi_2(t) = \frac{t^2 - 1}{\Phi_1(t)} = \frac{t^2 - 1}{t - 1} = t + 1 \]

Similarly,

\[ \Phi_3(t) = \frac{t^3 - 1}{t - 1} = t^2 + t + 1 \]

and

\[ \Phi_4(t) = \frac{t^4 - 1}{(t - 1)(t + 1)} = t^2 + 1 \]

and so on. The following table shows the first 15 cyclotomic polynomials computed in this manner. A curiosity of the table is that the coefficients of \( \Phi_n \) always seem to be 0, 1, or \(-1\). Is this always true? See Exercise 21.11.
\begin{tabular}{|c|c|}
\hline
\(n\) & \(\Phi_n(t)\) \\
\hline
1 & \(t - 1\) \\
2 & \(t + 1\) \\
3 & \(t^2 + t + 1\) \\
4 & \(t^2 + 1\) \\
5 & \(t^4 + t^3 + t^2 + t + 1\) \\
6 & \(t^2 - t + 1\) \\
7 & \(t^6 + t^5 + t^4 + t^3 + t^2 + t + 1\) \\
8 & \(t^4 + 1\) \\
9 & \(t^6 + t^3 + 1\) \\
10 & \(t^4 - t^3 + t^2 - t + 1\) \\
11 & \(t^{10} + t^9 + t^8 + t^7 + t^6 + t^5 + t^4 + t^3 + t^2 + t + 1\) \\
12 & \(t^4 - t^2 + 1\) \\
13 & \(t^{12} + t^{11} + t^{10} + t^9 + t^8 + t^7 + t^6 + t^5 + t^4 + t^3 + t^2 + t + 1\) \\
14 & \(t^6 - t^5 + t^4 - t^3 + t^2 - t + 1\) \\
15 & \(t^8 - t^7 + t^6 - t^4 + t^3 - t + 1\) \\
\hline
\end{tabular}

**Exercises**

21.1 Prove that in the notation of Section 21.3,

\[\zeta^j = \frac{1}{p - 1} \left( \sum_{\ell=0}^{p-2} \theta^{-j\ell} \zeta_{\ell} \right)\]

21.2 Prove that \(\Phi_{24}(t) = t^8 - t^4 + 1.\)

21.3 Show that the zeros of the \(d\)th cyclotomic polynomial can be expressed by radicals of degree at most \(\max(2, (d - 1)/2).\) (The 2 occurs because of the case \(d = 3.\))

21.4 Use the trigonometric identities \(\cos A \cos B = \frac{1}{2}(\cos(A + B) + \cos(A - B))\) and the like to prove that \(\Phi_{12}(t)\) is irreducible over \(\mathbb{Q}.\)

21.5 Prove that if \(\theta\) is a \((p - 1)\)th root of unity, then

\[1 + \theta^l + \theta^{2l} + \cdots + \theta^{(p-2)l} = \begin{cases} 0 & \text{if } l = 0 \\ p - 1 & \text{if } 1 \leq l \leq p - 2 \end{cases}\]

21.6 Prove that the coefficients of \(\Phi_p(t)\) are all 0, \(\pm 1\) when \(p\) is prime.

21.7 Prove that the coefficients of \(\Phi_{p^k}(t)\) are all 0, \(\pm 1\) when \(p\) is prime and \(k > 1.\)
21.8 If $m$ is odd, prove that $\Phi_{2m}(t) = \Phi_m(-t)$, and deduce that the coefficients of $\Phi_{2p^k}(t)$ are all $0, \pm 1$ when $p$ is an odd prime and $k > 1$.

21.9 If $p, q$ are distinct odd primes, find a formula for $\Phi_{pq}(t)$ and deduce that the coefficients of $\Phi_{pq}(t)$ are all $0, \pm 1$.

21.10 Relate $\Phi_{pa}(t)$ and $\Phi_{pa^k}(t)$ when $a, p$ are odd, $p$ is prime, $p$ and $a$ are coprime, and $k > 1$. Deduce that if the coefficients of $\Phi_{pa}(t)$ are all $0, \pm 1$, so are those of $\Phi_{pa^k}(t)$.

21.11 Show that the smallest $n$ such that the coefficients of $\Phi_m(t)$ might not all be $0, \pm 1$ is $n = 105$. If you have access to symbolic algebra software, or have an evening to spare, lots of paper, and are willing to be very careful checking your arithmetic, compute $\Phi_{105}(t)$ and see if some coefficient is not $0, \pm 1$.

21.12 Mark the following true or false.

a. Every root of unity in $\mathbb{C}$ has a nontrivial expression by radicals.

b. A primitive 11th root of unity in $\mathbb{C}$ can be expressed in terms of rational numbers using only square roots and fifth roots.

c. Any two primitive roots of unity in $\mathbb{C}$ have the same minimal polynomial over $\mathbb{Q}$.

d. The Galois group of $\Phi_n(t)$ over $\mathbb{Q}$ is cyclic for all $n$.

e. The Galois group of $\Phi_n(t)$ over $\mathbb{Q}$ is abelian for all $n$.

f. The coefficients of any cyclotomic polynomial are all equal to $0, \pm 1$. 
Chapter 22

Calculating Galois Groups

In order to apply Galois theory to specific polynomials, it is necessary to compute the corresponding Galois group. This is far from being a simple or straightforward task, and until now we have strenuously avoided it. Instead, we have either studied special equations whose Galois group is relatively easy to find (I did say "relatively"), resorted to special tricks, or obtained results that require only partial knowledge of the Galois group. The time has now come to squarely face up to the problem. This chapter contains relatively complete discussions for cubic and quartic polynomials. It also provides a general algorithm for equations of any degree, which is of theoretical importance but is too cumbersome to use in practice. More practical methods do exist, but they go beyond the scope of this book, see Hulpke (Internet).

22.1 Transitive Subgroups

We know that the Galois group \( \Gamma(f) \) of a polynomial \( f \) of degree \( n \) is (isomorphic to) a subgroup of the symmetric group \( S_n \). In classical terminology, \( \Gamma(f) \) permutes the roots of the equation \( f(t) = 0 \). Renumbering the roots changes \( \Gamma(f) \) to some conjugate subgroup of \( S_n \), so we need consider only the conjugacy classes of subgroups. However, \( S_n \) has rather a lot of conjugacy classes of subgroups, even for moderate \( n \) (say \( n \geq 6 \)). So the list of cases rapidly becomes unmanageable.

However, if \( f \) is irreducible (which we may always assume when solving \( f(t) = 0 \)), we can place a fairly stringent restriction on the subgroups that can occur. To state it we need:

**DEFINITION 22.1** Let \( G \) be a permutation group on \( \{1, \ldots, n\} \). Then \( G \) is transitive if for all \( i, j \leq n \) there exists \( \gamma \in G \) such that \( \gamma(i) = j \).

Equivalently, it is enough to show that for all \( i \leq n \) there exists \( \gamma \in G \) such that \( \gamma(1) = i \), because then there also exists \( \delta \in G \) such that \( \delta(1) = j \), whence \((\delta \gamma^{-1})(i) = j\).
Example 22.2

1. The Klein four-group $V$ is transitive on $\{1, 2, 3, 4\}$. The element 1 is mapped to:
   1. by the identity
   2. by $(12)(34)$
   3. by $(13)(24)$
   4. by $(14)(23)$

2. The cyclic group generated by $\alpha = (1234)$ is transitive on $\{1, 2, 3, 4\}$. In fact, $\alpha^i$ maps 1 to $i$ for $i = 1, 2, 3, 4$.

3. The cyclic group generated by $\beta = (123)$ is not transitive on $\{1, 2, 3, 4\}$. There is no power of $\beta$ that maps 1 to 4.

PROPOSITION 22.3

The Galois group of an irreducible polynomial $f$ is transitive on the set of zeros of $f$.

PROOF If $\alpha$ and $\beta$ are two zeros of $f$, then they have the same minimal polynomial, namely, $f$. By Theorem 4 and Proposition 4 there exists $\gamma$ in the Galois group such that $\gamma(\alpha) = \beta$.

Listing the (conjugacy classes of) transitive subgroups of $S_n$ is not as formidable as listing all (conjugacy classes of) subgroups. The transitive subgroups, up to conjugacy, have been classified for low values of $n$ by Conway, Hulpke, and MacKay (1998). There is only one such subgroup when $n = 2$, two when $n = 3$, and five when $n = 4, 5$. The magnitude of the task becomes apparent when $n = 6$; in this case, there are 16 transitive subgroups up to conjugacy. The number drops to seven when $n = 7$; in general, prime $n$ lead to fewer conjugacy classes of transitive subgroups than composite $n$ of similar size.

---

22.2 Bare Hands on The Cubic

As motivation, we begin with a cubic equation over $\mathbb{Q}$, where the answer can be obtained by direct "bare hands" methods. Consider a cubic polynomial

$$f(t) = t^3 - s_1t^2 + s_2t - s_3 \in \mathbb{Q}[t]$$

The coefficient $s_j$ are the elementary symmetric polynomials in the zeros $\alpha_1, \alpha_2, \alpha_3$, as in Section 18.2. If $f$ is reducible, then the calculation of its Galois group is easy; it
is the trivial group, which we denote by 1, if all zeros are rational, and \( S_2 \) otherwise. Thus we may assume that \( f \) is irreducible over \( \mathbb{Q} \).

Let \( \Sigma \) be the splitting field of \( f \),

\[
\Sigma = \mathbb{Q}(\alpha_1, \alpha_2, \alpha_3)
\]

By Proposition 22.3 the Galois group of \( f \) is a transitive subgroup of \( S_3 \), hence is either \( S_3 \) or \( A_3 \). Suppose for argument's sake that it is \( A_3 \). What does this imply about the zeros \( \alpha_1, \alpha_2, \alpha_3 \)? By the Galois correspondence, the fixed field \( A_3 \) of \( A_3 \) is \( \mathbb{Q} \). Now \( A_3 \) consists of the identity and the two cyclic permutations \((123)\) and \((132)\). Any expression in \( \alpha_1, \alpha_2, \alpha_3 \) that is invariant under cyclic permutations must, therefore, lie in \( \mathbb{Q} \). Two obvious expressions of this type are

\[
\phi = \alpha_1^2 \alpha_2 + \alpha_2^2 \alpha_3 + \alpha_3^2 \alpha_1
\]

and

\[
\psi = \alpha_1^2 \alpha_3 + \alpha_2^2 \alpha_1 + \alpha_3^2 \alpha_2
\]

Indeed, it can, with a little effort, be shown that

\[
A_3 = \mathbb{Q}(\phi, \psi)
\]

(see Exercise 22.3). In other words, the Galois group of \( f \) is \( A_3 \) if and only if \( \phi \) and \( \psi \) are rational.

This is useful only if we can calculate \( \phi \) and \( \psi \), which we now do. Because \( S_3 \) is generated by \( A_3 \) together with the transposition \((12)\), which interchanges \( \phi \) and \( \psi \), it follows that both \( \phi + \psi \) and \( \phi \psi \) are symmetric polynomials in \( \alpha_1, \alpha_2, \alpha_3 \). By Theorem 18.8 they are, therefore, polynomials in \( s_1, s_2, \) and \( s_3 \). We can compute these polynomials explicitly, as follows. We have

\[
\phi + \psi = \sum_{i \neq j} \alpha_i^2 \alpha_j
\]

Compare this with

\[
s_1 s_2 = (\alpha_1 + \alpha_2 + \alpha_3)(\alpha_1 \alpha_2 + \alpha_2 \alpha_3 + \alpha_3 \alpha_1) = \sum_{i \neq j} \alpha_i^2 \alpha_j + 3\alpha_1 \alpha_2 \alpha_3
\]

Since \( \alpha_1 \alpha_2 \alpha_3 = s_3 \), we deduce that

\[
\phi + \psi = s_1 s_2 - 3s_3
\]

Similarly,

\[
\phi \psi = \alpha_1^4 \alpha_2 \alpha_3 + \alpha_2^4 \alpha_3 \alpha_1 + \alpha_3^4 \alpha_1 \alpha_2 + \alpha_1^3 \alpha_2^3 \alpha_3 + \alpha_2^3 \alpha_3^3 \alpha_1 + \alpha_3^3 \alpha_1^3 \alpha_2 + 3\alpha_1^2 \alpha_2^2 \alpha_3^2
\]

\[
= s_3 (\alpha_1^3 + \alpha_2^3 + \alpha_3^3) + 3s_3^2 + \sum_{i < j} \alpha_i^2 \alpha_j^3
\]
Now

\[ s_1^3 = (\alpha_1 + \alpha_2 + \alpha_3)^3 = (\alpha_1^3 + \alpha_2^3 + \alpha_3^3) + 3 \sum_{i \neq j} \alpha_i^2 \alpha_j + 6\alpha_1 \alpha_2 \alpha_3 \]

so that

\[ \alpha_1^3 + \alpha_2^3 + \alpha_3^3 = s_1^3 - 6s_3 - 3(s_1s_2 - 3s_3) \]

Moreover,

\[ s_2^3 = (\alpha_1 \alpha_2 + \alpha_2 \alpha_3 + \alpha_3 \alpha_1)^3 = \sum_{i < j} \alpha_i^3 \alpha_j^3 + 3 \sum_{i,j,k} \alpha_i^3 \alpha_j^2 \alpha_k + 6\alpha_1^2 \alpha_2^2 \alpha_3^2 \]

\[ = \sum_{i < j} \alpha_i^3 \alpha_j^3 + 3s_3 \left( \sum_{i \neq j} \alpha_i^2 \alpha_j \right) + 6s_3^2 \]

Therefore,

\[ \sum_{i < j} \alpha_i^3 \alpha_j^3 = s_3^3 - 3s_3(s_1s_2 - 3s_3) - 6s_1^2 \]

\[ = s_2^3 - 3s_1s_2s_3 + 3s_3^2 \]

Putting all these together,

\[ \phi \psi = s_3 \left( s_1^3 - 3s_1s_2 + 3s_3 \right) + s_2^3 + 3s_3^2 - 3s_1s_2s_3 + 3s_3^2 \]

\[ = s_1^3s_3 + 9s_3^2 - 6s_1s_2s_3 + s_2^3 \]

Hence \( \phi \) and \( \psi \) are the roots of the quadratic equation

\[ t^2 - at + b = 0 \]

where

\[ a = s_1s_2 - 3s_3 \]

\[ b = s_3 \left( s_1^3 - 3s_1s_2 + 3s_3 \right) + s_2^3 + 3s_3^2 - 3s_1s_2s_3 + 3s_3^2 \]

By the formula for quadratics, this equation has rational zeros if and only if \( \sqrt{a^2 - 4b} \in \mathbb{Q} \). Direct calculation shows that

\[ a^2 - 4b = s_1^2s_2^2 + 18s_1s_2s_3 - 27s_3^2 - 4s_1^3s_3 - 4s_3^3 \]
We denote this expression by \( \Delta \), because it turns out to be the discriminant of \( f \). Thus we have proved:

**PROPOSITION 22.4**

Let \( f(t) = t^3 - s_1 t^2 + s_2 t - s_3 \in \mathbb{Q}[t] \) be irreducible over \( \mathbb{Q} \). Then its Galois group is \( \mathbb{A}_3 \) if

\[
\Delta = s_1^2 s_2^2 + 18 s_1 s_2 s_3 - 27 s_3^2 - 4 s_1^3 s_3 - 4 s_2^3
\]

is a perfect square in \( \mathbb{Q} \), and is \( S_3 \) otherwise.

**Example 22.5**

1. Let \( f(t) = t^3 + 3t + 1 \). This is irreducible, and

\[
s_1 = 0 \quad s_2 = 3 \quad s_3 = -1
\]

We find that \( \Delta = -27 - 4.27 = -135 \), which is not a square. Hence the Galois group is \( S_3 \).

2. Let \( f(t) = t^3 - 3t - 1 \). This is irreducible, and

\[
s_1 = 0 \quad s_2 = -3 \quad s_3 = 1
\]

Now \( \Delta = 81 \), which is a square. Hence the Galois group is \( A_3 \).

---

### 22.3 The Discriminant

More elaborate versions of the above method can be used to treat quartics or quintics, but in this form the calculations are very unstructured (see Exercise 22.6 for quartics). In this section we provide an interpretation of the expression \( \Delta \) above, and show that a generalization of it distinguishes between polynomials of degree \( n \) whose Galois groups are, or are not, contained in \( A_n \).

The definition of the discriminant generalizes to any field:

**DEFINITION 22.6** Suppose that \( f(t) \in K(t) \) and let its zeros in a splitting field be \( \alpha_1, \ldots, \alpha_n \). Let

\[
\delta = \prod_{i < j} (\alpha_i - \alpha_j)
\]

Then the discriminant \( \Delta(f) \) of \( f \) is

\[
\Delta(f) = \delta^2
\]
THEOREM 22.7
Let \( f \in K[t] \), where \( \text{char } K \neq 2 \). Then

1. \( \Delta(f) \in K \).

2. \( \Delta(f) = 0 \) if and only if \( f \) has a multiple zero.

3. \( \Delta(f) \) is a perfect square in \( K \) if and only if the Galois group of \( f \) is contained in the alternating group \( A_n \).

PROOF Let \( \sigma \in S_n \), acting by permutations of the \( \alpha_j \). It is easy to check that if \( \sigma \) is applied to \( \delta \), then it changes it to \( \pm \delta \), the sign being + if \( \sigma \) is an even permutation and - if \( \sigma \) is odd. (Indeed in many algebra texts the sign of a permutation is defined in this manner.) Therefore, \( \delta \in A_n \). Further, \( \Delta(f) = \delta^2 \) is unchanged by any permutation in \( S_n \), hence lies in \( K \). This proves (1).

Part (2) follows from the definition of \( \Delta(f) \).

Let \( G \) be the Galois group of \( f \), considered as a subgroup of \( S_n \). If \( \Delta(f) \) is a perfect square in \( K \), then \( \delta \in K \), so \( \delta \) is fixed by \( G \). Now odd permutations change \( \delta \) to \( -\delta \), and since \( \text{char}(K) \neq 2 \) we have \( \delta \neq -\delta \). Therefore, all permutations in \( G \) are even; that is, \( G \subset A_n \). Conversely, if \( G \subset A_n \), then \( \delta \in G^\perp = K \). Therefore, \( \Delta(f) \) is a perfect square in \( K \).

In order to apply Theorem 22.7, we must calculate \( \Delta(f) \) explicitly. Because it is a symmetric polynomial in the zeros \( \alpha_j \), it must be given by some polynomial in the elementary symmetric polynomials \( s_k \). Brute force calculations show that if \( f \) is a cubic polynomial, then

\[
\Delta(f) = s_1^2 s_2^2 + 18s_1 s_2 s_3 - 27s_3^2 - 4s_1^3 s_3 - 4s_2^3
\]

which is precisely the expression \( \Delta \) obtained in Proposition 22.4. Proposition 22.4 is thus a corollary of Theorem 22.7.

---

22.4 General Algorithm

We now describe a method which, in principle, will compute the Galois group of any polynomial. The practical obstacles involved in carrying it out are considerable for equations of even modestly high degree, but it does have the virtue of showing that the problem possesses a solution. More efficient algorithms have been invented, but to describe them would take us too far afield. Again, see Hulpke (Internet).

Suppose that

\[
f(t) = t^n - s_1 t^{n-1} + \cdots + (-1)^n s_n
\]
is a monic irreducible polynomial over a field $K$, having distinct zeros $\alpha_1, \ldots, \alpha_n$ in a splitting field $\Sigma$. That is, we assume $f$ is separable. The $s_k$ are the elementary symmetric polynomials in the $\alpha_j$. The idea is to consider not just how an element $\gamma$ of the Galois group $G$ of $f$ acts on $\alpha_1, \ldots, \alpha_n$, but how $\gamma$ acts on arbitrary linear combinations

$$\bar{\beta} = x_1\alpha_1 + \cdots + x_n\alpha_n$$

To make this action computable we form polynomials having zeros $\gamma(\beta)$ as $\gamma$ runs through $G$. To do so, define

$$\sigma_x(\beta) = x_{\sigma(1)}\alpha_1 + \cdots + x_{\sigma(n)}\alpha_n$$

$$\sigma_\alpha(\beta) = x_1\alpha_{\sigma(1)} + \cdots + x_n\alpha_{\sigma(n)}$$

By rearranging terms, we see that $\sigma_\alpha(\beta) = \sigma_x^{-1}(\beta)$.

Since $f$ has distinct zeros, $\sigma_x(\beta) \neq \tau_x(\beta)$ if $s \neq \tau$. Define the polynomial

$$Q = \prod_{\sigma \in S_n} (t - \sigma_x(\beta)) = \prod_{\sigma \in S_n} (t - \sigma_\alpha(\beta))$$

If we use the second expression for $Q$, expand in powers of $t$, collect like terms, and write all symmetric polynomials in the $\alpha_j$ as polynomials in the $s_k$, we find that

$$Q = \sum_{j=0}^{n!} \left( \sum_t g_t(s_1, \ldots, s_n) x_1^{i_1} \cdots x_n^{i_n} \right) t^j$$

where the $g_t$ are explicitly computable functions of $s_1, \ldots, s_n$. In particular, $Q \in K[t, x_1, \ldots, x_n]$.

Next we split $Q$ into a product of irreducibles,

$$Q = Q_1 \cdots Q_k$$

in $K[t, x_1, \ldots, x_n]$. In the ring $\Sigma[t, x_1, \ldots, x_n]$ we can write

$$Q_j = \prod_{\sigma \in S_j} (t - \sigma_x(\beta))$$

where $S_n$ is the disjoint union of the subsets $S_j$. We choose the labels so that the identity of $S_n$ is contained in $S_1$, and then $t - \beta$ divides $Q_1$ in $\Sigma[t, x_1, \ldots, x_n]$.

If $\sigma \in S_n$, then

$$Q = \sigma_x Q = (\sigma_x Q_1) \cdots (\sigma_x Q_k)$$

Hence $\sigma_x$ permutes the irreducible factors $Q_j$ of $Q$. Define

$$G = \{ \sigma \in S_n : \sigma_x Q_j = Q_1 \}$$
a subgroup of $S_n$. Then we have the following characterization of the Galois group of $f$:

**Theorem 22.8**

The Galois group $G$ of $f$ is isomorphic to the group $G$.

**Proof**  The subset $S_1$ of $S_n$ is, in fact, equal to $G$, because

$$S_1 = \{ \sigma : t - \sigma \beta \text{ divides } Q_1 \text{ in } \Sigma[t, x_1, \ldots, x_n] \}$$

$$= \{ \sigma : t - \beta \text{ divides } \sigma_x^{-1} Q_1 \text{ in } \Sigma[t, x_1, \ldots, x_n] \}$$

$$= \{ \sigma : \sigma_x^{-1} Q_1 = Q_1 \}$$

$$= G$$

Define

$$H = \prod_{\sigma \in G} (t - \sigma \beta) = \prod_{\sigma \in G} (t - \sigma_x \beta)$$

Clearly, $H \in K[t, x_1, \ldots, x_n]$. Now $H$ divides $Q$ in $\Sigma[t, x_1, \ldots, x_n]$ so $H$ divides $Q$ in $\Sigma(x_1, \ldots, x_n)$ so that $H$ divides $Q$ in $K[t, x_1, \ldots, x_n]$. Thus $H$ is a product of some of the irreducible factors $Q_j$ of $Q$. Because $y - \beta$ divides $H$, we know that $Q_1$ is one of these factors. Therefore, $Q_1$ divides $H$ in $K[t, x_1, \ldots, x_n]$ so $G \subseteq G$.

Conversely, if $\gamma \in G$, then

$$\gamma(Q_1) = \prod_{\sigma \in S_1} (t - \gamma_x \sigma_x \beta) = \prod_{\sigma \in S_1} (t - \gamma^{-1} \sigma_x \beta)$$

$$= \gamma \sigma_x^{-1} \prod_{\sigma \in S_1} (t - \sigma_x \beta) = \gamma \sigma^{-1}(Q_1)$$

But $Q_1 \in K[t, x_1, \ldots, x_n]$, so $\gamma \sigma^{-1}(Q_1) = Q_1$. So $\gamma \in G$, whence $G \subseteq G$. 

**Example 22.9**

Suppose that $\alpha$, $\beta$ are the zeros of a quadratic polynomial $t^2 - At + B = 0$, where $A = \alpha + \beta$ and $B = \alpha \beta$. The polynomial $Q$ takes the form

$$Q = (t - \alpha x - \beta y)(t - \alpha y - \beta x)$$

$$= t^2 - t(\alpha x + \beta y + \alpha y + \beta x) + [(\alpha^2 + \beta^2)xy + \alpha \beta(x^2 + y^2)]$$

$$= t^2 - t(Ax + Ay) + [(A^2 - 2B)xy + B(x^2 + y^2)]$$

This is either irreducible or has two linear factors. The condition for irreducibility is that

$$A^2(x + y)^2 - 4[(A^2 - 2B)xy + B(x^2 + y^2)]$$
is not a perfect square. But this is equal to

\[(A^2 - 4B)(x - y)^2\]

which is a perfect square if and only if \(A^2 - 4B\) is a perfect square. Thus the Galois group \(G\) is trivial if \(A^2 - 4B\) is a perfect square, and is cyclic of order 2 if \(A^2 - 4B\) is not a perfect square.

---

**Exercises**

22.1 Let \(f \in K[t]\) where \(\text{char}(K) \neq 2\). If \(\Delta(f)\) is not a perfect square in \(K\) and \(G\) is the Galois group of \(f\), show that \(G \cap A_n\) has fixed field \(K(\delta)\).

22.2 Find an expression for the discriminant of a quartic polynomial.

22.3 In the notation of Proposition 22.4, show that \(A_3^\dagger = \mathbb{Q}(\phi, \psi)\).

22.4 Show that \(\delta\) in Definition 22.6 is given by the Vandermonde determinant (see Exercise 2.5)

\[
\begin{vmatrix}
1 & 1 & \ldots & 1 \\
\alpha_1 & \alpha_2 & \ldots & \alpha_n \\
\alpha_1^2 & \alpha_2^2 & \ldots & \alpha_n^2 \\
\vdots & \vdots & \ddots & \vdots \\
\alpha_1^{n-1} & \alpha_2^{n-1} & \ldots & \alpha_n^{n-1}
\end{vmatrix}
\]

Multiply this matrix by its transpose and take the determinant to show that \(\Delta(f)\) is equal to

\[
\begin{vmatrix}
\lambda_n & \lambda_1 & \ldots & \lambda_{n-1} \\
\lambda_1 & \lambda_2 & \ldots & \lambda_n \\
\vdots & \vdots & \ddots & \vdots \\
\lambda_{n-1} & \lambda_n & \ldots & \lambda_{2n-2}
\end{vmatrix}
\]

where \(\lambda_k = \alpha_k^k + \ldots + \alpha_n^k\). Hence, using Exercise 8.5, compute \(\Delta(f)\) when \(f\) is of degree 2, 3, or 4. Check your result is the same as that obtained previously.

22.5* If \(f(t) = t^n + at + b\), show that

\[\Delta(f) = \mu_{n+1}n^n b^{n-1} - \mu_n (n-1)^{n-1} a^n\]

where \(\mu_n\) is 1 if \(n\) is a multiple of 4 and is \(-1\) otherwise.
22.6* Show that any transitive subgroup of $S_4$ is one of $S_4$, $A_4$, $D_8$, $V$, or $Z_4$, defined as follows:

\[
A_4 = \text{alternating group of degree 4} \\
V = \{1, (12)(34), (13)(24), (14)(23)\} \\
D_8 = \text{group generated by } V \text{ and } (12) \\
Z_4 = \text{group generated by } (1234)
\]

22.7* Let $f$ be a monic irreducible quartic polynomial over a field $K$ of characteristic $\neq 2, 3$ with discriminant $\Delta$. Let $g$ be its resolvent cubic, defined by the same formula that we derived for the general quartic, and let $M$ be a splitting field for $g$. Show that:

a. $\Gamma(f) \cong S_4$ if and only if $\Delta$ is not a square in $K$ and $g$ is irreducible over $K$.

b. $\Gamma(f) \cong A_4$ if and only if $\Delta$ is a square in $K$ and $g$ is irreducible over $K$.

c. $\Gamma(f) \cong D_8$ if and only if $\Delta$ is not a square in $K$, $g$ splits over $K$, and $f$ is irreducible over $M$.

d. $\Gamma(f) \cong V$ if and only if $\Delta$ is a square in $K$ and $g$ splits over $K$.

e. $\Gamma(f) \cong Z_4$ if and only if $\Delta$ is not a square in $K$, $g$ splits over $K$, and $f$ is reducible over $M$.

22.8 Prove that \{(123), (456), (14)\} generates a transitive subgroup of $S_6$.

22.9 Mark the following true or false.

a. Every nontrivial normal subgroup of $S_n$ is transitive.

b. Every nontrivial subgroup of $S_n$ is transitive.

c. Every transitive subgroup of $S_n$ is normal.

d. Every transitive subgroup of $S_n$ has order divisible by $n$.

e. The Galois group of any irreducible cubic polynomial over a field of characteristic zero is isomorphic either to $S_3$ or to $A_3$.

f. If $K$ is a field of characteristic zero in which every element is a perfect square, then the Galois group of any irreducible cubic polynomial over $K$ is isomorphic to $A_3$.

g. If $K$ is a field of characteristic zero in which every element is a perfect square, then the Galois group of any irreducible $n$th degree polynomial over $K$ is isomorphic to $A_n$. 
Chapter 23

Algebraically Closed Fields

Back to square one.

In Chapter 2 we proved the Fundamental Theorem of Algebra using some plausible topological facts about winding numbers. It is possible to give an almost algebraic proof, in which the only extraneous information required is that every polynomial of odd degree over \( \mathbb{R} \) has a real zero. This follows immediately from the continuity of polynomials over \( \mathbb{R} \) and the fact that an odd degree polynomial changes sign somewhere between \(-\infty\) and \(+\infty\).

We now give this almost-algebraic proof, which applies to a slight generalization. The main property of \( \mathbb{R} \) that we require is that \( \mathbb{R} \) is an ordered field, with a relation \( \leq \) that satisfies the usual properties. So we start by defining an ordered field. Then we develop some group theory, a far-reaching generalization of Cauchy’s Theorem due to the Norwegian mathematician Ludwig Sylow, about the existence of certain subgroups of prime power order in any finite group. Finally, we combine Sylow’s Theorem with the Galois correspondence to prove the main theorem, which we set in the general context of an algebraically closed field.

23.1 Ordered Fields and Their Extensions

The first proof of the Fundamental Theorem of Algebra was given by Gauss in his doctoral dissertation of 1799 under the title (in Latin) *A New Proof that Every Rational Integral Function of One Variable can be Resolved into Real Factors of the First or Second Degree*. Gauss was being polite in using the word “new,” because his was the first genuine proof. Even his proof, from the modern viewpoint, has gaps, but these are topological in nature and not hard to fill. In Gauss’s day they were not considered to be gaps at all. Gauss’s proof can be found in Hardy (1960, p. 492).

There are other proofs. One of a more recondite nature uses complex variable theory (see Titchmarsh, 1960, p. 118) and is probably the proof most commonly encountered in an undergraduate course. There is a proof by Clifford (1968, p. 20) that is almost entirely algebraic; the idea is to show that any irreducible polynomial over \( \mathbb{R} \) is of degree 1 or 2. The proof we shall give here is essentially due to Legendre, but his original proof had gaps which we fill by using Galois theory.
It is unreasonable to ask for a purely algebraic proof of the theorem, as the real numbers (and hence the complex numbers) are defined in terms of analytic concepts such as Cauchy sequences, Dedekind cuts, or completeness in an ordering.

We begin by abstracting some properties of the reals.

**DEFINITION 23.1** An ordered field is a field $K$ with a relation $\leq$ such that:

1. $k \leq k$ for all $k \in K$.
2. $k \leq l$ and $l \leq m$ implies $k \leq m$ for all $k, l, m \in K$.
3. $k \leq l$ and $l \leq k$ implies $k = l$ for all $k, l \in K$.
4. If $k, l \in K$, then either $k \leq l$ or $l \leq k$.
5. If $k, l, m \in K$ and $k \leq l$, then $k + m \leq l + m$.
6. If $k, l, m \in K$ and $k \leq l$ and $0 \leq m$, then $km \leq lm$.

The relation $\leq$ is an ordering on $K$. The relations $<$, $\geq$, $>$ are defined in the obvious way, as are the concepts positive and negative.

Examples of ordered fields are $\mathbb{Q}$ and $\mathbb{R}$. We need two simple consequences of the definition of an ordered field.

**LEMMA 23.2**

Let $K$ be an ordered field. Then for any $k \in K$ we have $k^2 \geq 0$. Further, the characteristic of $K$ is zero.

**PROOF** If $k \geq 0$, then $k^2 \geq 0$ by (6). So by (3) and (4) we may assume $k < 0$. If now we had $-k < 0$ it would follow that

$$0 = k + (-k) < k + 0 = k$$

a contradiction. So $-k \geq 0$, whence $k^2 = (-k)^2 \geq 0$. This proves the first statement.

We now know that $1 = 1^2 > 0$, so for any finite $n$ the number

$$n \cdot 1 = 1 + \cdots + 1 > 0$$

implying that $n \cdot 1 \neq 0$ and $K$ must have characteristic 0.

We quote the following properties of $\mathbb{R}$.

**LEMMA 23.3**

$\mathbb{R}$, with the usual ordering, is an ordered field. Every positive element of $\mathbb{R}$ has a square root in $\mathbb{R}$. Every odd degree polynomial over $\mathbb{R}$ has a zero in $\mathbb{R}$.
These are all proved in any course in analysis and depend on the fact that a polynomial function on \( \mathbb{R} \) is continuous.

\[ \text{23.2 Sylow’s Theorem} \]

Next, we set up the necessary group theory. Sylow’s Theorem is based on the concept of a \( p \)-group.

**DEFINITION 23.4** Let \( p \) be a prime. A finite group \( G \) is a \( p \)-group if its order is a power of \( p \).

For example, the dihedral group \( D_8 \) is a 2-group. If \( n \geq 3 \), then the symmetric group \( S_n \) is never a \( p \)-group for any prime \( p \).

The \( p \)-groups have many pleasant properties (and many unpleasant ones, but we shall not dwell on their Dark Side). One is:

**THEOREM 23.5**

If \( G \neq 1 \) is a finite \( p \)-group, then \( G \) has nontrivial centre.

**PROOF** The class equation (14.2) of \( G \) reads

\[ p^n = |G| = 1 + |C_2| + \cdots + |C_r| \]

and Corollary 14.12 implies that \( |C_j| = p^{n_j} \) for some \( n_j \geq 0 \). Now \( p \) divides the right-hand side of the class equation so that at least \( p - 1 \) values of \( |C_j| \) must be equal to 1. But if \( x \) lies in a conjugacy class with only one element, then \( g^{-1}xg = x \) for all \( g \in G \); that is, \( gx = xg \). Hence \( x \in Z(G) \). Therefore, \( Z(G) \neq 1 \).

From this we easily deduce:

**LEMMA 23.6**

If \( G \) is a finite \( p \)-group of order \( p^n \), then \( G \) has a series of normal subgroups

\[ 1 = G_0 \subseteq G_1 \subseteq \cdots \subseteq G_n = G \]

such that \( |G_j| = p^j \) for all \( j = 0, \ldots, n \).

**PROOF** Use induction on \( n \). If \( n = 0 \), all is clear. If not, let \( Z = Z(G) \neq 1 \) by Theorem 23.5. Since \( Z \) is an abelian group of order \( p^n \) it has an element of order \( p \). The cyclic subgroup \( K \) generated by such an element has order \( p \) and is normal in
G since \( K \subseteq Z \). Now \( G/K \) is a \( p \)-group of order \( p^{n-1} \), and by induction there is a series of normal subgroups

\[ K/K = G_1/K \subseteq \cdots \subseteq G_n/K \]

where \( |G_j/K| = p^{j-1} \). But then \( |G_j| = p^j \) and \( G_j \triangleleft G \). If we let \( G_0 = 1 \), the result follows.

**COROLLARY 23.7**
Every finite \( p \)-group is soluble.

**PROOF** The quotients \( G_{j+1}/G_j \) of the series afforded by Lemma 23.6 are of order \( p \), and hence are cyclic and, in particular, abelian.

In 1872 Sylow discovered some fundamental theorems about the existence of \( p \)-groups inside given finite groups. We shall need one of his results in this chapter. We state all of his results, though we shall prove only the one that we require.

**THEOREM 23.8 (Sylow)**
Let \( G \) be a finite group of order \( p^a r \) where \( p \) is prime and does not divide \( r \). Then

1. \( G \) possesses at least one subgroup of order \( p^a \).
2. All such subgroups are conjugate in \( G \).
3. Any \( p \)-subgroup of \( G \) is contained in one of order \( p^a \).
4. The number of subgroups of \( G \) of order \( p^a \) leaves remainder 1 on division by \( p \).

This result motivates:

**DEFINITION 23.9** If \( G \) is a finite group of order \( p^a r \) where \( p \) is prime and does not divide \( r \), then a Sylow \( p \)-subgroup of \( G \) is a subgroup of \( G \) of order \( p^a \).

In this terminology, Theorem 8 says that for finite groups Sylow \( p \)-subgroups exist for all primes \( p \), are all conjugate, are the maximal \( p \)-subgroups of \( G \), and occur in numbers restricted by condition (4).

**PROOF OF 8 (PART 1)** We use induction on \( |G| \). The theorem is obviously true for \( |G| = 1 \) or 2. Let \( C_1, \ldots, C_s \) be the conjugacy classes of \( G \), and let \( c_j = |C_j| \). The class equation of \( G \) is

\[ p^a r = c_1 + \cdots + c_s \]  \hspace{1cm} (23.1)
Let $Z_j$ denote the centralizer in $G$ of some element $x_j \in C_j$, and let $n_j = |Z_j|$. By Lemma 14.11

\[ n_j = p^a r / c_j \]  
\((23.2)\)

Suppose first that some $c_j$ is greater than 1 and not divisible by $p$. Then by (23.2) $n_j < p^a r$ and is divisible by $p^a$. Hence by induction $Z_j$ contains a subgroup of order $p^a$. Therefore, we may assume that for all $j = 1, \ldots, s$ either $c_j = 1$ or $p | c_j$. Let $z = |Z(G)|$. As in Theorem 23.5, $z$ is the number of values of $i$ such that $c_j = 1$. So $p^a r = z \mid kp$ for some integer $k$. Hence $p$ divides $z$, and $G$ has a nontrivial centre $Z$ such that $p$ divides $|Z|$. By Lemma 14.14, the group $Z$ has an element of order $p$, which generates a subgroup $P$ of $G$ of order $p$. Since $P \subseteq Z$ it follows that $P \triangleleft G$. By induction $G/P$ contains a subgroup $S/P$ of order $p^{a-1}$, whence $S$ is a subgroup of $G$ of order $p^a$ and the theorem is proved. 

**Example 23.10**

Let $G = S_4$ so that $|G| = 24$. According to Sylow’s theorem, $G$ must have subgroups of orders 3 and 8. Subgroups of order 3 are easy to find: any 3-cycle, such as $(123)$ or $(134)$ or $(234)$, generates such a group. We shall find a subgroup of order 8. Let $\forall$ be the Klein four-group, which is normal in $G$. Let $\tau$ be any 2-cycle, generating a subgroup $T$ of order 2. Then $\forall \cap T = 1$, and $\forall T$ is a subgroup of order 8. (It is isomorphic to $D_8$.)

Analogues of Sylow’s theorem do not work as soon as we go beyond prime powers. Exercise 14.6 illustrates this point.

---

### 23.3 The Algebraic Proof

With Sylow’s Theorem under our belt, all that remains is to set up a little more Galois-theoretic machinery.

**Lemma 23.11**

Let $K$ be a field of characteristic zero, such that for some prime $p$ every finite extension $M$ of $K$ with $M \neq K$ has $[M : K]$ divisible by $p$. Then every finite extension of $K$ has degree a power of $p$.

**Proof** Let $N$ be a finite extension of $K$. The characteristic is zero, so $N : K$ is separable. By passing to a normal closure we may assume $N : K$ is also normal, so that the Galois correspondence is bijective. Let $G$ be the Galois group of $N : K$, and let $P$ be a Sylow $p$-subgroup of $G$. The fixed field $P^\perp$ has degree $[P^\perp : K]$ equal to the index of $P$ in $G$ (Theorem 12.1(3)), but this is prime to $p$. By hypothesis, $P^\perp = K$, so $P = G$. Then $[N : K] = |G| = p^n$ for some $n$. 

\[ \square \]
THEOREM 23.12
Let $K$ be an ordered field in which every positive element has a square root and every odd-degree polynomial has a zero. Then $K(i)$ is algebraically closed, where $i^2 = -1$.

PROOF $K$ cannot have any extensions of finite odd degree greater than 1. For suppose $[M : K] = r > 1$ where $r$ is odd. Let $\alpha \in M \setminus K$ have minimal polynomial $m$. Then $\partial m$ divides $r$, so is odd. By hypothesis, $m$ has a zero in $K$, and so is reducible, contradicting Lemma 6. Hence every finite extension of $K$ has even degree over $K$. The characteristic of $K$ is 0 by Lemma 23.2, so by Lemma 23.11 every finite extension of $K$ has 2-power degree.

Let $M \neq K(i)$ be any finite extension of $K(i)$ where $i^2 = -1$. By taking a normal closure we may assume $M : K$ is normal, so the Galois group of $M : K$ is a 2-group. Using Lemma 23.6 and the Galois correspondence, we can find an extension $N$ of $K(i)$ of degree $[N : K(i)] = 2$. By the formula for solving quadratic equations, $N = K(i)(\alpha)$ where $\alpha^2 \in K(i)$. But if $a, b \in K$, then it can be shown, by squaring the right-hand side, that

$$\sqrt{a + bi} = \sqrt{\frac{a + \sqrt{a^2 + b^2}}{2}} + i \sqrt{\frac{-a + \sqrt{a^2 + b^2}}{2}}$$

where the square root of $a^2 + b^2$ is the positive one, and the signs of the other two square roots are chosen to make their product equal to $b$. The square roots exist in $K$ because the elements inside them are positive, as is easily checked.

Therefore, $\alpha \in K(i)$, so that $N = K(i)$, which contradicts our assumption on $N$. Therefore, $M = K(i)$, and $K(i)$ has no finite extensions of degree $> 1$. Hence any irreducible polynomial over $K(i)$ has degree 1, otherwise a splitting field would have finite degree $> 1$ over $K(i)$. Therefore, $K(i)$ is algebraically closed. \[\square\]

COROLLARY 23.13 (Fundamental Theorem of Algebra)
The field $\mathbb{C}$ of complex numbers is algebraically closed.

PROOF Put $\mathbb{R} = K$ in Theorem 23.12 and use Lemma 23.3. \[\square\]

Exercises

23.1 Show that a subgroup or a quotient of a $p$-group is again a $p$-group. Show that an extension of a $p$-group by a $p$-group is a $p$-group.

23.2 Prove that every group of order $p^2$ (with $p$ prime) is abelian. Hence show that there are exactly two non-isomorphic groups of order $p^2$ for any prime number $p$. 

23.3 Show that a field $K$ is algebraically closed if and only if $L : K$ algebraic implies $L = K$.

23.4 Show that every algebraic extension of $\mathbb{R}$ is isomorphic to $\mathbb{R} : \mathbb{R}$ or $\mathbb{C} : \mathbb{R}$.

23.5 Show that $\mathbb{C}$, with the traditional field operations, cannot be given the structure of an ordered field. If we allow different field operations, can the set $\mathbb{C}$ be given the structure of an ordered field?

23.6 Prove the theorem whose statement is the title of Gauss’s doctoral dissertation mentioned at the beginning of the chapter. ("Rational integral function" was his term for "polynomial.")

23.7 Suppose that $K : \mathbb{Q}$ is a finitely generated extension. Prove that there exists a $\mathbb{Q}$-monomorphism $K \rightarrow \mathbb{C}$. (Hint: Use cardinality considerations to adjoin transcendental elements, and algebraic closure of $\mathbb{C}$ to adjoin algebraic elements.) Is the theorem true for $\mathbb{R}$ rather than $\mathbb{C}$?

23.8 Mark the following true or false.
   a. Every soluble group is a $p$-group.
   b. Every Sylow subgroup of a finite group is soluble.
   c. Every simple $p$-group is abelian.
   d. The field $\mathbb{A}$ of algebraic numbers defined in Example 17.4 is algebraically closed.
   e. There is no ordering on $\mathbb{C}$ making it into an ordered field.
   f. Every ordered field has characteristic zero.
   g. Every field of characteristic zero can be ordered.
   h. In an ordered field, every square is positive.
   i. In an ordered field, every positive element is a square.
Chapter 24

Transcendental Numbers

One final task awaits attention, and it will take us in a completely new direction. To complete the proof of the impossibility of squaring the circle, and so crown 3000 years of mathematical effort, we must prove that \( \pi \) is transcendental over \( \mathbb{Q} \). (In this chapter the word “transcendental” will be understood to mean transcendental over \( \mathbb{Q} \).) The proof we give is analytic, which should not be surprising since \( \pi \) is best defined analytically. The techniques involve symmetric polynomials integration, differentiation, and some manipulation of inequalities, together with a healthy lack of respect for apparently complicated expressions.

It is not at all obvious that transcendental real (or complex) numbers exist. That they do was first proved by Liouville in 1844, by considering the approximation of reals by rationals. It transpires that algebraic numbers cannot be approximated by rationals with more than a certain speed (see Exercises 24.5 to 24.7). Finding a transcendental number reduces to finding a number that can be approximated more rapidly than the known bound for algebraic numbers. Liouville showed that this is the case for the real number

\[
\xi = \sum_{n=1}^{\infty} 10^{-n!}
\]

but no naturally occurring number was proved transcendental until Charles Hermite, in 1873, proved that \( e \), the “base of natural logarithms,” is. Using similar methods, Ferdinand Lindemann demonstrated the transcendence of \( \pi \) in 1882.

Meanwhile Georg Cantor, in 1874, had produced a revolutionary proof of the existence of transcendental numbers, without actually constructing any. His proof (see Exercises 24.1 to 24.4) used set-theoretic methods, and was one of the earliest triumphs of Cantor’s theory of infinite cardinals. When it first appeared, the mathematical world viewed it with great suspicion, but nowadays it scarcely raises an eyebrow.

We shall prove four theorems in this chapter. In each case the proof proceeds by contradiction, and the final blow is dealt by the following simple result:

**Lemma 24.1**

Let \( f : \mathbb{Z} \to \mathbb{Z} \) be a function such that \( f(n) \to 0 \) as \( n \to +\infty \). Then there exists \( N \in \mathbb{Z} \) such that \( f(n) = 0 \) for all \( n \geq N \).
24.1 Irrationality

Lindemann’s proof is ingenious and intricate. To prepare the way we shall first prove some simpler theorems of the same general type. These results are not needed for Lindemann’s proof, but familiarity with the ideas is. The first theorem was initially proved by Johann Heinrich Lambert in 1770 using continued fractions, although it is often credited to Legendre.

THEOREM 24.2
The real number \( \pi \) is irrational.

PROOF Consider the integral

\[
I_n = \int_{-1}^{1} (1 - x^2)^n \cos(\alpha x) \, dx
\]

Integrating by parts,

\[
\alpha^2 I_n - 2n(2n - 1)I_{n-1} - 4n(n - 1)I_{n-2}
\]

if \( n \geq 2 \). By induction on \( n \),

\[
\alpha^{2n+1} I_n = n! (P \sin(\alpha) + Q \cos(\alpha))
\]

(24.1)

where \( P \) and \( Q \) are polynomials in \( \alpha \) of degree \( < 2n + 1 \) with integer coefficients. The term \( n! \) comes from the factor \( 2n(2n - 1) \) of (24.1).

Assume, for a contradiction, that \( \pi \) is rational, so that \( \pi = a/b \) where \( a, b \in \mathbb{Z} \) and \( b \neq 0 \). Let \( \alpha = \pi/2 \) in (24.2). Then

\[
J_n = a^{2n+1} I_n / n!
\]

is an integer. By definition,

\[
J_n = \frac{a^{2n+1}}{n!} \int_{-1}^{1} (1 - x^2)^n \cos \frac{\pi x}{2} \, dx
\]

The integrand is \( > 0 \) for \( -1 < x < 1 \), so \( J_n > 0 \). Hence \( J_n \neq 0 \) for all \( n \). But

\[
|J_n| \leq \frac{|a|^{2n+1}}{n!} \int_{-1}^{1} \cos \frac{\pi x}{2} \, dx
\]

\[
\leq C |a|^{2n+1} / n!
\]
where $C$ is a constant. Hence $J_n \to 0$ as $n \to +\infty$. This contradicts Lemma 24.1, so the assumption that $\pi$ is rational is false.

The next, slightly stronger, result was proved by Legendre in his Éléments de Géométrie of 1794, which, as we remarked in the Historical Introduction, greatly influenced the young Galois.

**THEOREM 24.3**
The real number $\pi^2$ is irrational.

**PROOF** Assume if possible that $\pi^2 = a/b$ where $a, b \in \mathbb{Z}$ and $b \neq 0$. Define

$$f(x) = x^n(1-x)^n/n!$$

and

$$G(x) = b^n \left( \pi^{2n} f(x) - \pi^{2n-2} f''(x) + \cdots + (-1)^n \pi^0 f^{(2n)}(x) \right)$$

where the superscripts indicate derivatives. We claim that any derivative of $f$ takes integer values at 0 and 1. Recall Leibniz's rule for differentiating a product:

$$\frac{d^m}{dx^m} (uv) = \sum \binom{m}{r} \frac{d^r u}{dx^r} \frac{d^{m-r} v}{dx^{m-r}}$$

If both factors $x^n$ or $(1-x)^n$ are differentiated fewer than $n$ times, then the value of the corresponding term is 0 whenever $x = 0$ or 1. If one factor is differentiated $n$ or more times, then the denominator $n!$ is cancelled out. Hence $G(0)$ and $G(1)$ are integers. Now

$$\frac{d}{dx} \left[ G'(x) \sin(\pi x) - \pi G(x) \cos(\pi x) \right] = \left[ G''(x) + \pi^2 G(x) \right] \sin(\pi x)$$

$$= b^n \pi^{2n+2} f(x) \sin(\pi x)$$

since $f(x)$ is a polynomial in $x$ of degree $2n$, so that $f^{(2n+2)}(x) = 0$. And this expression is equal to

$$\pi^2 a^n \sin(\pi x) f(x)$$

Therefore,

$$\pi \int_0^1 a^n \sin(\pi x) f(x) dx = \left[ \frac{G'(x) \sin(\pi x)}{\pi} - G(x) \cos(\pi x) \right]_0^1$$

$$= G(0) + G(1)$$
which is an integer. As before, the integral is not zero. But

\[
\left| \int_0^1 a^n \sin(n\pi x) f(x) \, dx \right| \leq |a|^n \int_0^1 \left| \sin(n\pi x) \right| |f(x)| \, dx
\]

\[
\leq |a|^n \int_0^1 \frac{|x^n(1-x)^n|}{n!} \, dx
\]

\[
\leq \frac{1}{n!} \int_0^1 |(ax)^n(1-x)^n| \, dx
\]

which tends to 0 as \( n \) tends to \(+\infty\). The usual contradiction completes the proof. \( \square \)

24.2 Transcendence of e

We move on from irrationality to the far more elusive transcendence. Hermite's original proof was simplified by Karl Weierstrass, David Hilbert, Adolf Hurwitz, and Paul Gordan, and it is the simplified proof that we give here. The same holds for the proof of Lindemann's theorem in the next section.

THEOREM 24.4 (Hermite)
The real number e is transcendental.

PROOF Assume that e is not transcendental. Then

\[ a_m e^m + \cdots + a_1 e + a_0 = 0 \]

where without loss of generality we may suppose that \( a_j \in \mathbb{Z} \) for all \( j \) and \( a_0 \neq 0 \). Define

\[ f(x) = \frac{x^{p-1}(x-1)^p(x-2)^p \cdots (x-m)^p}{(p-1)!} \]

where \( p \) is an arbitrary prime number. Then \( f \) is a polynomial in \( x \) of degree \( mp+p-1 \). Put

\[ F(x) = f(x) + f'(x) + \cdots + f^{(mp+p-1)}(x) \]

and note that \( f^{(mp+p)}(x) = 0 \). We calculate:

\[ \frac{d}{dx} [e^{-x} F(x)] = e^{-x} (F'(x) - F(x)) = -e^{-x} f(x) \]
Hence for any $j$

$$a_j \int_0^j e^{-x} f(x) dx = a_j [-e^{-x} F(x)]_0^j = a_j F(0) - a_j e^{-j} F(j)x$$

Multiplying by $e^j$ and summing over $j = 0, 1, \ldots, m$,

$$\sum_{j=0}^m \left( a_j e^j \int_0^j e^{-x} f(x) dx \right) = F(0) \sum_{j=0}^m a_j e^j - \sum_{j=0}^m a_j F(j)$$

$$= - \sum_{j=0}^m \sum_{i=0}^{mp+p-1} a_j f^{(i)}(j)$$

from the equation supposedly satisfied by $e$.

We claim that each $f^{(i)}(j)$ is an integer, and that this integer is divisible by $p$ unless $j = 0$ and $i = p - 1$. To establish the claim we use Leibniz's rule again; the only nonzero terms arising when $j \neq 0$ come from the factor $(x - j)^p$ being differentiated exactly $p$ times. Since $p!/(p-1)! = p$, all such terms are integers divisible by $p$. In the exceptional case $j = 0$, the first nonzero term occurs when $i = p - 1$, and then

$$f^{(p-1)}(0) = (-1)^p \ldots (-m)^p$$

Subsequent nonzero terms are all multiples of $p$. The value of Equation (24.3) is, therefore,

$$Kp + a_0 (-1)^p \ldots (-m)^p$$

for some $K \in \mathbb{Z}$. If $p > \max(m, |a_0|)$, then the integer $a_0 (-1)^p \ldots (-m)^p$ is not divisible by $p$. So for sufficiently large primes $p$ the value of Equation (6.3) is an integer not divisible by $p$, hence not zero.

Now we estimate the integral. If $0 \leq x \leq m$,

$$|f(x)| \leq m^{mp+p-1}/(p-1)!$$

so

$$\left| \sum_{j=0}^m a_j e^j \int_0^j e^{-x} f(x) dx \right| \leq \sum_{j=0}^m |a_j e^j| \int_0^j \frac{m^{mp+p-1}}{(p-1)!} dx$$

$$\leq \sum_{j=0}^m |a_j e^j| j \frac{m^{mp+p-1}}{(p-1)!}$$

which tends to $0$ as $p$ tends to $+\infty$.

This is the usual contradiction. Therefore, $e$ is transcendental.
24.3 Transcendence of $\pi$

The proof that $\pi$ is transcendental involves the same sort of trickery as the previous results, but is far more elaborate. At several points in the proof we use properties of symmetric polynomials from Chapter 18.

**THEOREM 24.5 (Lindemann)**

The real number $\pi$ is transcendental.

**PROOF** Suppose for a contradiction that $\pi$ is a zero of some nonzero polynomial over $\mathbb{Q}$. Then so is $i\pi$, where $i = \sqrt{-1}$. Let $\theta_1(x) \in \mathbb{Q}[x]$ be a polynomial with zeros $\alpha_1 = i\pi, \alpha_2, \ldots, \alpha_n$. By a famous theorem of Euler,

$$e^{i\pi} + 1 = 0$$

so

$$(e^{\alpha_1} + 1)(e^{\alpha_2} + 1) \cdots (e^{\alpha_n} + 1) = 0 \quad (24.4)$$

We now construct a polynomial with integer coefficients whose zeros are the exponents $\alpha_1, \ldots, \alpha_n$ of $e$ that appear in the expansion of the product in (24.4). For example, terms of the form

$$e^{\alpha_s} \cdot e^{\alpha_t} \cdot 1 \cdot 1 \cdot 1 \cdots$$

give rise to exponents $\alpha_s + \alpha_t$. Taken over all pairs $s, t$ we get exponents of the form $\alpha_1 + \alpha_2, \ldots, \alpha_{n-1} + \alpha_n$. The elementary symmetric polynomials of these are symmetric in $\alpha_1, \ldots, \alpha_n$, so by Theorem 18.8 they can be expressed as polynomials in the elementary symmetric polynomials of $\alpha_1, \ldots, \alpha_n$. These in turn are expressible in terms of the coefficients of the polynomial $\theta_1$ whose zeros are $\alpha_1, \ldots, \alpha_n$. Hence the pairs $\alpha_s + \alpha_t$ satisfy a polynomial equation $\theta_2(x) = 0$ where $\theta_2$ has rational coefficients. Similarly, the sums of $k$ of the $\alpha$'s are zeros of a polynomial $\theta_k(x)$ over $\mathbb{Q}$. Then

$$\theta_1(x)\theta_2(x) \cdots \theta_n(x)$$

is a polynomial over $\mathbb{Q}$ whose zeros are the exponents of $e$ in the expansion of Equation (24.4). Dividing by a suitable power of $x$ and multiplying by a suitable integer we obtain a polynomial $\theta(x)$ over $\mathbb{Z}$, whose zeros are the nonzero exponents $\beta_1, \ldots, \beta_r$ of $e$ in the expansion of Equation (24.4).

Now (24.4) takes the form

$$e^{\beta_1} + \cdots + e^{\beta_r} + e^0 + \cdots + e^0 = 0$$
that is,

\[ e^{\beta_1} + \cdots + e^{\beta_r} + k = 0 \]  \hspace{1cm} (24.5)

where \( k \in \mathbb{Z} \). The term \( 1 \cdot 1 \cdots 1 \) occurs in the expansion, so \( k > 0 \).

Suppose that

\[ \theta(x) = c x^r + c_1 x^{r-1} + \cdots + c_r \]

We know that \( c_r \neq 0 \) because 0 is not a zero of \( \theta \). Define

\[ f(x) = \frac{e^s x^{p-1} \theta(x)^p}{(p-1)!} \]

where \( s = rp - 1 \) and \( p \) is any prime number. Define also

\[ F(x) = f(x) + f'(x) + \cdots + f^{(s+p+r-1)}(x) \]

and note that \( f^{(s+p+r)}(x) = 0 \). As before,

\[ \frac{d}{dx}[e^{-x}F(x)] = -e^{-x}f(x) \]

Hence

\[ e^{-x}F(x) - F(0) = - \int_0^x e^{-y}f(y)dy \]

Putting \( y = \lambda x \) we get

\[ F(x) - e^x F(0) = -x \int_0^1 \exp[(1 - \lambda)x]f(\lambda x)d\lambda \]

Let \( x \) range over \( \beta_1, \ldots, \beta_r \) and sum; by (24.5)

\[ \sum_{j=1}^r F(\beta_j) + k F(0) = - \sum_{j=1}^r \beta_j \int_0^1 \exp[(1 - \lambda)\beta_j]f(\lambda \beta_j)d\lambda \]  \hspace{1cm} (24.6)

We claim that for all sufficiently large \( p \) the left-hand side of (24.6) is a nonzero integer. To prove the claim, observe that

\[ \sum_{j=1}^r f^{(i)}(\beta_j) = 0 \]

if \( 0 < t < p \). Each derivative \( f^{(i)}(\beta_j) \) with \( t \geq p \) has a factor \( p \), since we must differentiate \( \theta(x)^p \) at least \( p \) times to obtain a nonzero term. For any such \( t \),

\[ \sum_{j=1}^r f^{(i)}(\beta_j) \]
is a symmetric polynomial in the $\beta_j$ of degree $\leq s$. Thus by Theorem 18.8 it is a polynomial of degree $\leq s$ in the coefficients $c_i/c$. The factor $c^s$ in the definition of $f(x)$ makes this into an integer. So for $t \geq p$,

$$\sum_{j=1}^r f^{(t)}(\beta_j) = pk_t$$

for suitable $k_t \in \mathbb{Z}$.

Now we look at $F(0)$. Computations show that

$$f^{(t)}(0) = \begin{cases} 0 & (t \leq p - 2) \\ c^s c_r^p & (t = p - 1) \\ l_t p & (t \geq p) \end{cases}$$

for suitable $l_t \in \mathbb{Z}$. Consequently, the left-hand side of (24.6) is

$$mp + kc^s c_r^p$$

for some $m \in \mathbb{Z}$. Now $k \neq 0$, $c \neq 0$, and $c_r \neq 0$. If we take

$$p > \max(k, |c|, |c_r|)$$

then the left hand side of (24.6) is an integer not divisible by $p$, so is nonzero.

The last part of the proof is routine; we estimate the size of the right-hand side of (24.6). Now

$$|f(\lambda\beta_j)| \leq \frac{|c|^p |\beta_j|^{p-1}(m(j))^p}{(p-1)!}$$

where

$$m(j) = \sup_{0 \leq \lambda \leq 1} |\theta(\lambda\beta_j)|$$

Therefore,

$$\left| - \sum_{j=1}^r \beta_j \int_0^1 \exp[(1 - \lambda)\beta_j] f(\lambda\beta_j) d\lambda \right| \leq \sum_{j=1}^r \frac{|\beta_j|^p |c^s||m(j)|^p B}{(p-1)!}$$

where

$$B = \max_j \left| \int_0^1 \exp[(1 - \lambda)\beta_j] d\lambda \right|$$

Thus the expression tends to 0 as $p$ tends to $+\infty$. By the standard contradiction, $\pi$ is transcendental.
Exercises

The first four exercises outline Cantor’s proof of the existence of transcendental numbers, using what are now standard results on infinite cardinals.

24.1 Prove that $\mathbb{R}$ is uncountable; that is, there is no bijection $\mathbb{Z} \to \mathbb{R}$.

24.2 Define the height of a polynomial

$$f(t) = a_0 + \cdots + a_n t^n \in \mathbb{Z}[t]$$

to be

$$h(f) = n + |a_0| + \cdots + |a_n|$$

Prove that there are only a finite number of polynomials over $\mathbb{Z}$ of given height $h$.

24.3 Show that any algebraic number satisfies a polynomial equation over $\mathbb{Z}$. Using Exercise 24.2 show that the algebraic numbers form a countable set.

24.4 Combine Exercises 24.1 and 24.3 to show that transcendental numbers exist. The next three exercises give Liouville’s proof of the existence of transcendental numbers.

24.5* Suppose that $x$ is irrational and that

$$f(x) = a_n x^n + \cdots + a_0 = 0$$

where $a_0, \ldots, a_n \in \mathbb{Z}$. Show that if $p, q \in \mathbb{Z}$ and $q \neq 0$, and $f(p/q) \neq 0$, then

$$|f(p/q)| \geq 1/q^n$$

24.6* Now suppose that $x - 1 < p/q < x + 1$ and $p/q$ is nearer to $x$ than any other zero of $f$. There exists $M$ such that $|f'(y)| < M$ if $x - 1 < y < x + 1$. Use the mean value theorem to show that

$$|p/q - x| \geq M^{-1} q^{-n}$$

Hence show that for any $r > n$ and $K > 0$ there exist only finitely many $p$ and $q$ such that

$$|p/q - x| < Kq^{-r}$$

24.7 Use this result to prove that $\sum_{n=1}^{\infty} 10^{-n}$ is transcendental.

24.8 Prove that $z \in \mathbb{C}$ is transcendental if and only if its real part is transcendental or its imaginary part is transcendental.
24.9 Mark the following true or false.

a. \( \pi \) is irrational.
b. All irrational numbers are transcendental.
c. Any rational multiple of \( \pi \) is transcendental.
d. \( \pi + i\sqrt{2} \) is transcendental.
e. \( e \) is irrational.
f. If \( \alpha \) and \( \beta \) are real and transcendental, then so is \( \alpha + \beta \).
g. If \( \alpha \) and \( \beta \) are real and transcendental, then so is \( \alpha + i\beta \).
h. Transcendental numbers form a subring of \( \mathbb{C} \).
i. The field \( \mathbb{Q}(\pi) \) is isomorphic to \( \mathbb{Q}(t) \) for any indeterminate \( t \).
j. \( \mathbb{Q}(\pi) \) and \( \mathbb{Q}(e) \) are non-isomorphic fields.
k. \( \mathbb{Q}(\pi) \) is isomorphic to \( \mathbb{Q}(\pi^2) \).
